Chapter 1

General Introduction

1–1. Utility of Pyrrolidine Derivatives

A variety of organic compounds are used as biologically active molecules in the fields of pharmaceuticals and natural product chemistry. In general, it is known that the biological activity of these molecules depends not only on their molecular structures but also on their stereochemistry.¹ Therefore, developing the method for the precise preparation of stereoisomer has long been an important research subject in synthetic organic chemistry and medicinal chemistry. Stereodivergent synthesis² that can access multiple stereoisomers including diastereomers from common starting materials has been actively pursued in recent years because it is expected to improve the efficiency of drug discovery (Figure 1-1).

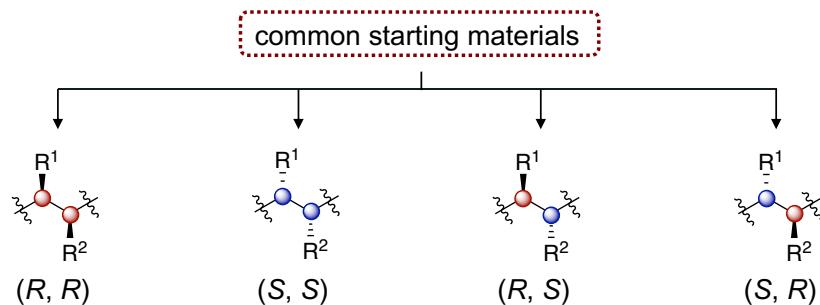

Figure 1-1. Stereodivergent synthesis.

Nitrogen-containing five-membered cyclic compounds, pyrrolidines, are included in the basic skeleton of complex amino acids and in numerous biologically active molecules and asymmetric catalysts.³ Pyrrolidines are rich in structural diversity, and many of them exist with additional cyclic skeletons such as fused- and spirocyclic-structures. The stereochemistry of these pyrrolidines shows that 2,5-*trans* pyrrolidines, whose substituents at the 2- and 5-positions of the pyrrolidine ring have a *trans* relationship, are as common as 2,5-*cis* pyrrolidines (Figure 1-2). For example, kaitocephalin⁴ (glutamate receptor agonist), which was isolated from *Eupenicillium shearii* PF1191, and a pyrrolidine that exhibits anti-HCV (hepatitis C virus) activity⁵ are 2,5-*cis* substituted. (7*S*)-Kaitocephalin in a 2,5-*trans* fashion, which was synthesized in

2016, has been shown to exhibit significantly high α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic (AMPA)-type selectivity, whereas the naturally occurring molecule ((7*R*)-kaitocephalin) activates both N-methyl-D-aspartate (NMDA) and AMPA-types.⁶ Furthermore, pyrrolidine derivatives that exhibit influenza neuraminidase inhibitory activity⁷ and MDM2-p53 activity⁸ have the 2,5-*trans* configuration. Therefore, it is strongly desired to develop efficient synthetic methods for the preparation of pyrrolidine derivatives rich in structural and stereodivergency. In particular, the development of stereodivergent synthetic methods for 2,5-*cis/trans* pyrrolidines is an important research issue because it can lead to the efficient creation of new biologically active compounds.

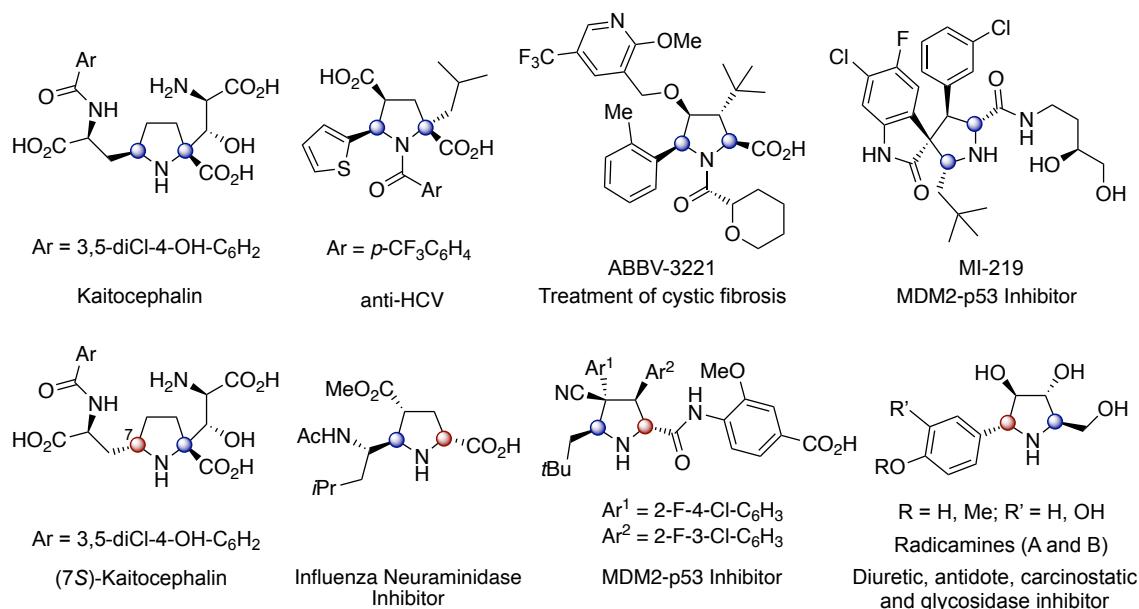

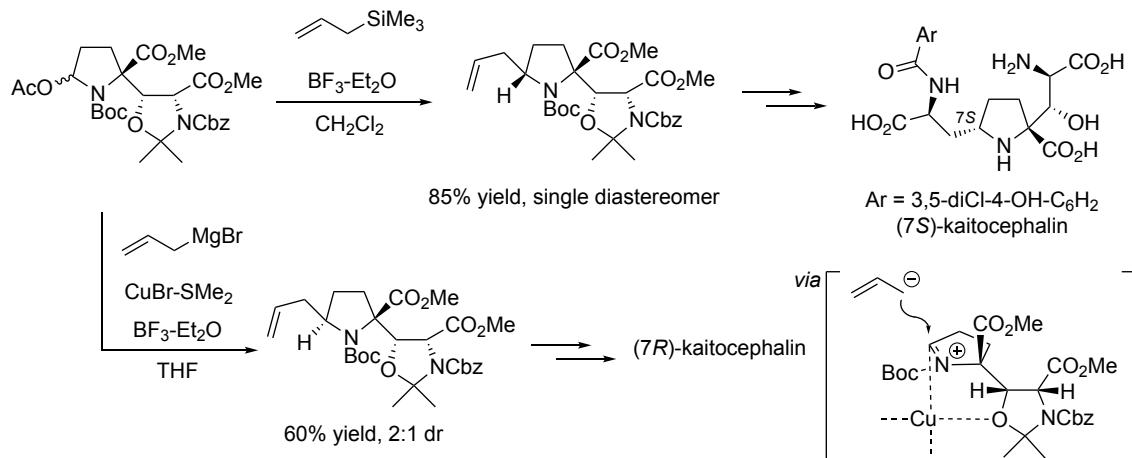

Figure 1-2. Examples of biologically active pyrrolidine with 2,5-*cis/trans* configuration.

1-2. Stereodivergent Synthesis of 2,5-*cis/trans* Pyrrolidines

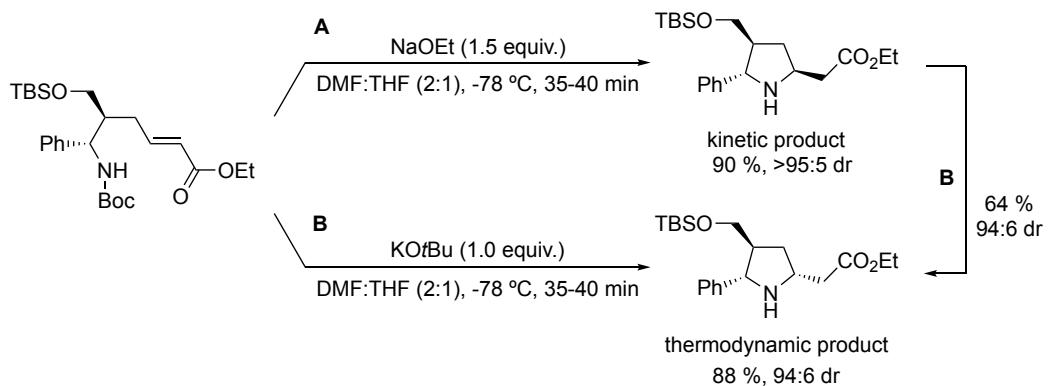

To date, several pioneering studies have been conducted on the stereodivergent synthesis of 2,5-*cis/trans* pyrrolidines. The diastereodivergent synthesis of (7*R*)-and (7*S*)-kaitocephalin described above was achieved using different types of nucleophiles in the allylation reaction (Scheme 1-1).^{6a} Specifically, the allylation reaction of the starting AcO-substituted pyrrolidine proceeded by treatment with allyl trimethyl silane and boron trifluoride diethyl ether complex, affording (7*S*)-pyrrolidine intermediates. In contrast, the diastereomeric (7*R*)-form was afforded as the main product when the same synthetic intermediate was subjected to an allyl copper reagent, which was prepared from an allyl Grignard reagent and a copper dimethyl sulfide bromide complex. It has been proposed that the heterocyclic substituent bonded to the pyrrolidine ring plays the role of an auxiliary group, i.e., the coordination of the oxygen atom of the substituent to the copper center can lead to the (7*R*)-diastereomer. Both intermediates can be converted to kaitocephalin, accomplishing the diastereodivergent synthesis of (7*S*)- and (7*R*)-kaitocephalins.

Scheme 1-1. Diastereodivergent synthesis of (7*R*)- and (7*S*)-kaitocephalin.

The stereodivergent synthesis of 2,5-*cis/trans* pyrrolidines using intramolecular amination reactions, which is one of the typical pyrrolidine synthesis methods, was reported by Scheider and co-workers in 2009 (Scheme 1-2).⁹ This is an example of an

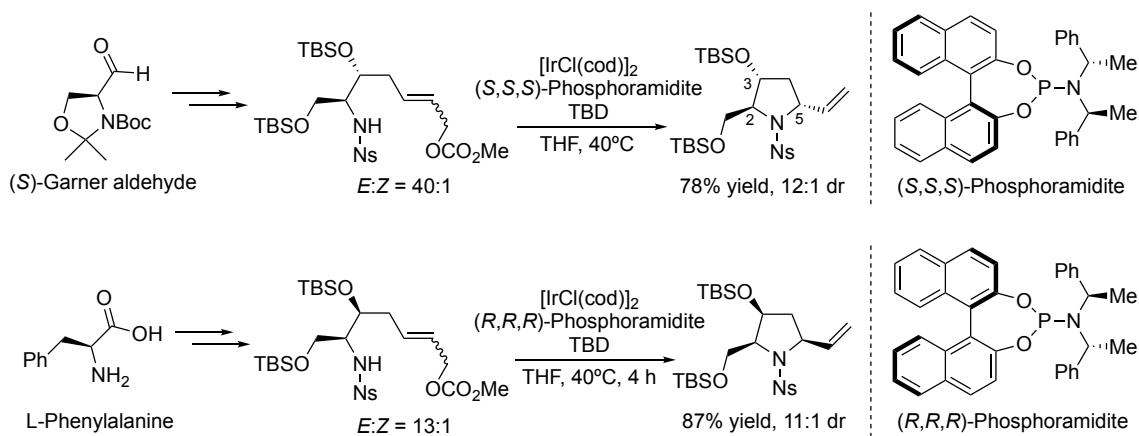

intramolecular aza-Michael addition reaction, which proceeds by the action of a base on a compound that has been prepared by the asymmetric Mannich reaction and subsequent silyl protection. The 2,5-*trans* pyrrolidine is generated with high diastereoselectivity when sodium ethoxide (NaOEt) is used as a base. In contrast, the corresponding 2,5-*cis* configured pyrrolidine is produced when potassium *tert*-butoxide ($\text{KO}t\text{Bu}$) is used instead of NaOEt . Additionally, the isomerization reaction of the 2,5-*trans* pyrrolidine to the 2,5-*cis* one proceeds under condition **B** using $\text{KO}t\text{Bu}$. This suggests that the aza-Michael addition giving the pyrrolidine ring is a reversible reaction and the 2,5-*trans* configured pyrrolidine is kinetically generated under condition **A** using NaOEt . Conversely, the 2,5-*cis* pyrrolidine produced by using $\text{KO}t\text{Bu}$ in condition **B** is the thermodynamically favorable product.

Scheme 1-2. Diastereodivergent synthesis using intramolecular aza-Michael addition reaction.

In 2014, Takahata and co-workers reported a method based on iridium-catalyzed stereoselective allylic amination reactions for the diastereodivergent preparation of 2,5-*cis/trans* pyrrolidines (Scheme 1-3).¹⁰ First, the cyclization precursor was prepared from (*S*)-Garner aldehyde with high stereoselectivity. The stereoselective allylic amination to give 2,5-*trans* substituted pyrrolidines took place by the action of an iridium complex and a phosphoramidite-based chiral ligand on this precursor. In contrast, the corresponding 2,5-*cis* substituted pyrrolidines can be obtained from cyclization precursors derived from L-phenylalanine by using the enantiomer of the above-described chiral ligand. The

products can be used as synthetic intermediates of (+)-bulgecinine and (+)-preussin, respectively.

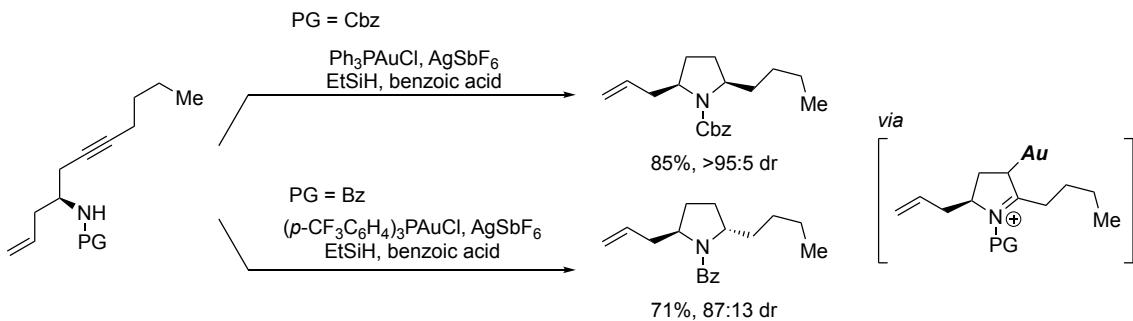

Scheme 1-3. Diastereodivergent synthesis using intramolecular allylic amination reaction.

A diastereodivergent synthetic method using gold-catalyzed intramolecular amination of internal alkynes followed by silane reduction has recently been reported by Fuwa and co-workers (Scheme 1-4).¹¹ The absolute configuration of the constructed stereocenter is determined when the silane reduction of the iminium intermediate takes place, not during the intramolecular amination process. The stereoselectivity was controlled by the protecting group on the amino group and the ligand of the gold catalyst. Specifically, the 2,5-*cis* substituted pyrrolidine was obtained with excellent diastereoselectivity by the intramolecular reaction using the Cbz-protected cyclization precursor. The 2,5-*trans* substituted pyrrolidine was formed as the major product when Bz-protected amino alkynes were applied to the reaction. These 2,5-*cis/trans* pyrrolidines have been used as synthetic intermediates for (+)-monomorine and (+)-indolizidine, respectively.

As described above, these pioneering diastereodivergent syntheses of 2,5-*cis/trans* pyrrolidines have been achieved either by direct introduction of substituents into preconstructed chiral pyrrolidine rings or by intramolecular amination reactions using chiral cyclization precursors as starting materials. Indeed, almost all of these methods

used chiral molecules as starting materials, impacting their efficiency due to the necessity of preparing chiral reaction precursors, which may take several steps. In other words, efficient synthetic methods for the diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines have rarely been developed. Therefore, the development of new methodologies is desired in organic synthetic chemistry.

Scheme 1-4. Diastereodivergent synthesis using intramolecular amination of internal alkynes and subsequent silane reduction.

1–3. Catalytic Asymmetric 1,3–Dipolar Cycloaddition of Imino Esters

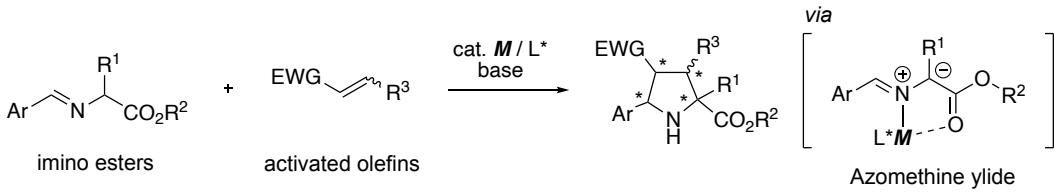

1–3–1. General Background

Along with intramolecular amination, the 1,3-dipolar cycloaddition (1,3-DC) of azomethine ylides with activated alkenes is an efficient synthetic method for the preparation of pyrrolidine derivatives.¹² Azomethine ylides are active species with a cationic nitrogen atom and an adjacent anionic carbon atom. They lead to pyrrolidine rings by (3+2) cycloaddition with activated olefins. Classically, azomethine ylides are known to be generated by the decarboxylation of imines formed by the condensation reaction of *N*-alkylamino acids and aldehydes under high temperatures.^{12c} Lithium azaallyl anions, which are generated by the action of strong bases such as organolithium reagents on imine compounds without active substituents such as carbonyl groups, are also known to give pyrrolidine compounds by the (3+2) cycloaddition reaction.^{12cd,13} In

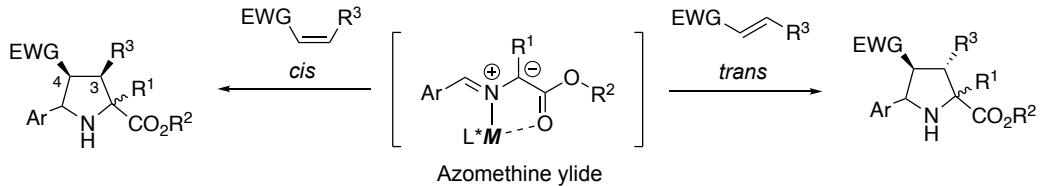

addition, the desilylation of silyl-substituted azomethine ylide precursors with activators such as acids and the thermal ring-opening reaction of aziridines can be used for pyrrolidine synthesis.^{12c,14} However, these classical methods usually require extreme activators such as strong acids, bases, or heat. Therefore, they are not suitable as a methodology for accurately creating multiple stereoisomers.

In contrast, the reaction of imino esters as the azomethine ylide precursors is very promising for the catalytic asymmetric synthesis of pyrrolidines (Figure 1-3a).¹⁵ In this method, the use of a chiral metal complex catalyst as a Lewis acid in combination with a base converts the imino ester to the azomethine ylide complex whose imine and carbonyl groups coordinate to the metal center. The chiral azomethine ylide then undergoes an asymmetric (3+2) cycloaddition reaction with activated olefins, which leads to the stereoselective synthesis of pyrrolidine derivatives. Although this cycloaddition reaction can construct multiple chiral centers in one step, many stereoisomers can be theoretically formed, i.e., if there are four chiral centers, a total of 16 stereoisomers could be obtained. However, the relative configuration of the 3- and 4-positions of the pyrrolidine ring in this cycloaddition reaction reflects the geometric isomerism of the olefin used, giving the corresponding cycloadducts (Figure 1-3b). For example, the relative configuration of the 3- and 4-positions will be *trans* if a *trans*-olefin is used. Thus, there are four accessible diastereoisomers (*endo*, *exo*, *endo'*, *exo'*) in the reaction, with their corresponding enantiomers (Figure 1-3c). The *endo*-adducts refer to a compound in which the carbonyl group at the 2-position is placed *cis* to the aromatic substituent at the 5-position, and the electron-withdrawing substituent at the 4-position is *cis* to these substituents. When the relative configuration of the 2- and 5-positions is *cis* and the substituent at the 4-position is *trans* to that at the 5-position, these adducts are classified as *exo*-diastereomers. In contrast to the above-described 2,5-*cis* cycloadducts, *endo'/exo'*-adducts are in the 2,5-*trans* configuration. Namely, the *endo'*-adduct refers to the 4,5-*cis* configuration in 2,5-*trans* adducts, and the *exo'*-adducts refer to the 4,5-*trans* configuration.

(a) Metal complex-catalyzed (3+2) cycloaddition of imino esters

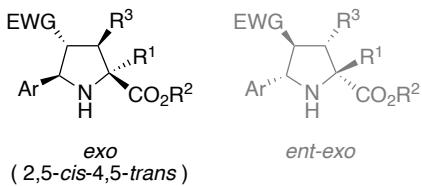

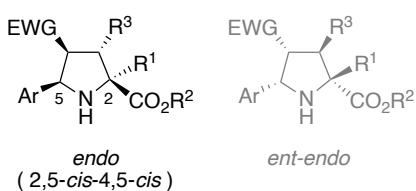

(b) Relationship of olefin and 3,4-relative configuration

Usual stereochemistry (2,5-*cis*)

Unusual stereochemistry (2,5-*trans*)

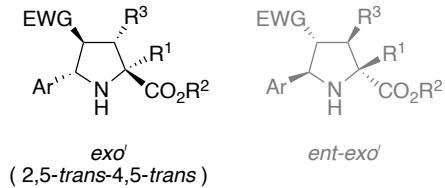

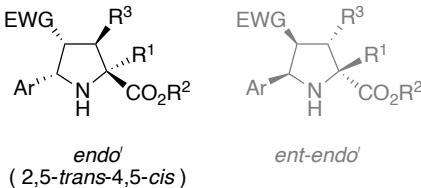

Figure 1-3. Asymmetric 1,3-DC of imino esters and the accessible stereoisomers.

The above-classified stereochemistry of the pyrrolidines is determined by both the reaction mechanism and transition state. This reaction generally constructs the pyrrolidine ring by a concerted cycloaddition, in which two bonds are formed almost simultaneously. The electrons in the HOMO of the azomethine ylide flow into the LUMO of the electron-deficient olefin, forming the two bonds. The reacting azomethine ylide is a bidentate complex of N and O atoms, and the aromatic substituents are *cis* to the carbonyl groups. Therefore, when this azomethine ylide undergoes cycloaddition reactions, the 2,5-*cis* adducts are preferentially formed because their stereochemistry depends on the conformation of the starting materials. When the electron-withdrawing group of the

activated olefins reacts when facing the metal center, the *endo*-form is given, while the *exo*-adducts are formed when the electron-withdrawing group faces the opposite direction. The *endo/exo*-diastereoselectivity depends on the stability of the transition state. Not only the reactivity of the activated olefins but also the catalyst used affect the *endo/exo*-diastereoselectivity. On the other hand, 2,5-*trans* adducts such as *endo'/exo'* are rarely formed from this azomethine ylide. To induce such 2,5-*trans* adducts from the *cis*-formed azomethine ylides, it is necessary to go through a stepwise cycloaddition process that switches reaction faces in the middle of the reaction. This is unfavorable for the reaction mechanism compared to the above-described concerted pathway and similar stepwise pathways.

The asymmetric 1,3-DC of imino esters with activated alkenes was first reported by Grigg and co-workers in 1991 using stoichiometric amounts of chiral Co(II) and Mn(II) complex catalysts.¹⁶ Subsequently, in 2002, Zhang, Jorgensen, and co-workers reported the first catalytic asymmetric 1,3-DC reaction.¹⁷ Since then, various teams, including our research group, have developed a variety of catalysts based on their concepts. In particular, copper and silver complexes have been applied frequently in recent years, and chiral bidentate ligands such as P, N-, P, S-, and P, P- have been found to work effectively (Figure 1-4).¹⁵ For example, Zhou and co-workers first reported in 2005 that AgOAc/FcPHOX complexes efficiently catalyze the 1,3-DC of imino esters with dimethyl maleate to give the corresponding *endo*-adducts with high enantioselectivity.¹⁸ The corresponding *endo*-adducts are obtained with high enantioselectivity when *N*-phenylmaleimide, *tert*-butyl acrylate, or dimethyl fumarate are used as activated olefins under the Ag/FcPHOX-catalyzed condition. The copper/Fesulphos complex developed by Carretero and co-workers in the same year has also been shown to be highly catalytically active in this reaction.¹⁹ Other ligands such as ThioClickFerrophos (TCF)²⁰ developed by Fukuzawa and co-workers and 1,3-dihydroimidazolepyridine (DHIPOH)²¹ developed by Deng and co-workers show high stereoselectivity as silver and copper complexes, respectively. TF-BiphamPhos, an asymmetric ligand developed by Wang and co-workers, catalyzes this asymmetric (3+2)

cycloaddition efficiently as both silver and copper complexes.²² In some cases, the axially chiral biaryl diphosphine ligands BINAP and Segphos,²³ which are typical asymmetric ligands, and the monodentate phosphine ligand phosphoramidite²⁴ have also been reported to exhibit high stereoselectivity in this reaction.

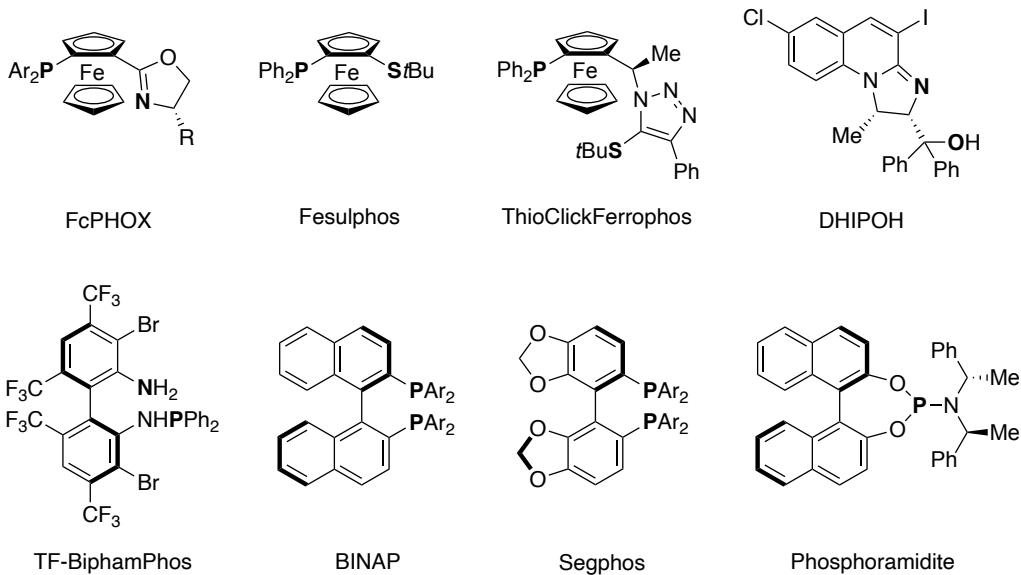

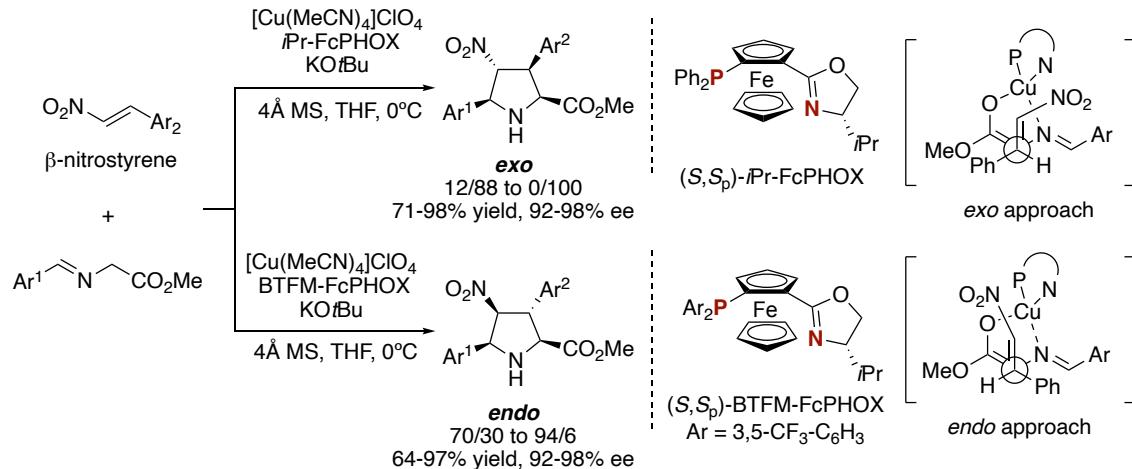

Figure 1-4. Some ligands employed in the copper and silver-catalyzed conditions.

In the Diels-Alder reaction, which is a representative cycloaddition, it has been shown that the *endo*-adduct, which is kinetically favorable, is preferentially formed due to secondary orbital interactions.¹² The contribution of this orbital interaction is small in the 1,3-DC, where steric bulk and electronic properties play a major role. Therefore, the *endo*-adducts are not always preferentially formed in this reaction, and many examples of *exo*-diastereoselectivity indicate these other properties may play a major role. One trend supported by several previous studies is that the diastereoselectivity depends on the nature of the metal center of the catalyst. Specifically, the copper complex-catalyzed reaction often proceeds with *exo*-diastereoselectivity, whereas the silver complex-catalyzed one tends to produce the *endo*-diastereomers. It is usually explained that the interaction between the carbonyl group of the dipole and the silver center stabilizes the transition state for the *endo*-adducts. When the copper complex catalysts are employed, the interactions between the dipole and ligand often affect the stereoselectivity. Based on

the above, representative examples that successfully achieved the *endo/exo*-diastereodivergent synthesis are summarized in this chapter.

1-3-2. *endo/exo*-Diastereodivergent Synthesis

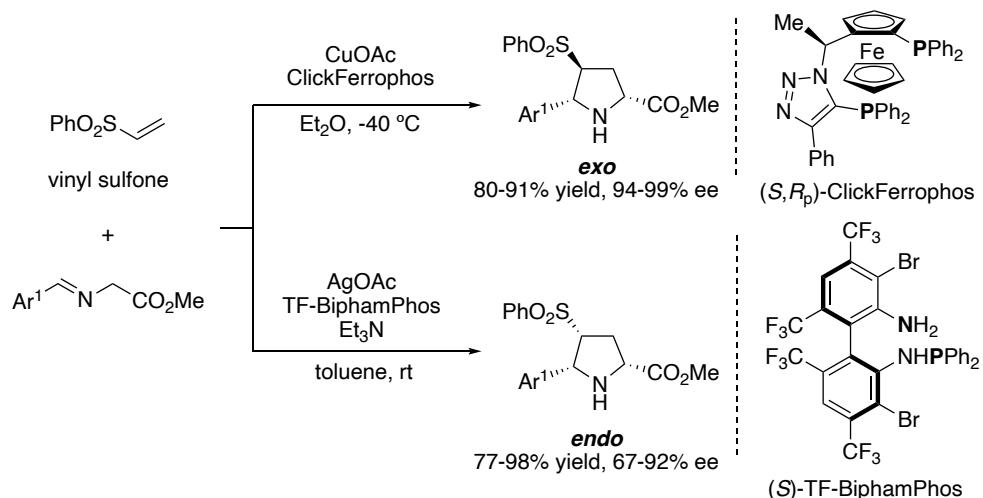

In 2006, Hou and co-workers achieved the pioneering *endo/exo*-diastereodivergent synthesis in the catalytic asymmetric 1,3-DC of imino esters with nitro alkenes (Scheme 1-5).²⁵ When a common copper/FcPHOX complex was used as the catalyst, the *exo*-adducts were produced with high diastereo- and enantioselectivity. In contrast, when an asymmetric ligand with electron-withdrawing substituents CF₃ on the aromatic ring attached to the phosphorus atom was used, the diastereoselectivity switched to give the corresponding *endo*-adducts in a highly enantioselective manner. DFT calculations were used to explain the reversal of diastereoselectivity, and a reasonable transition state was proposed for each. The transition state giving the *exo*-adducts was energetically favored with the nitro group of the active alkene positioned closer to the nitrogen atom on the ligand. On the other hand, a transition state was proposed in which the nitro group was positioned close to the phosphorus atom of the ligand to give the *endo*-adducts. The electrostatic interaction between the copper center and the nitro group of the activated olefins is controlled by an aromatic substituent on the phosphorus atom of the FcPHOX, and the *endo/exo*-diastereoselectivity is successfully achieved. A similar example of the

Scheme 1-5. Ligand-controlled *endo/exo*-diastereodivergent 1,3-DC of nitro olefins.

diastereodivergent synthesis controlled by two types of chiral ligands in the copper complex-catalyzed reaction of imino esters with nitro olefins was achieved by Cossío and co-workers in 2012.²⁶

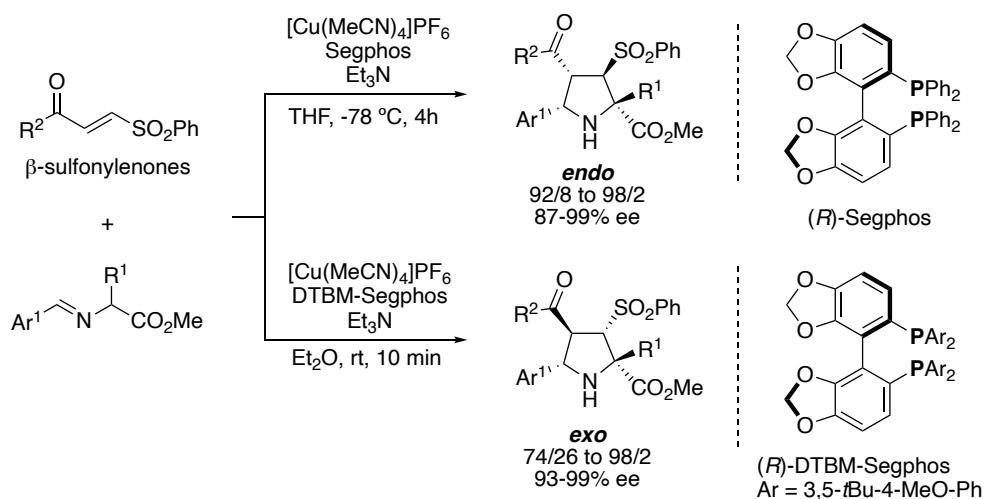

The catalytic asymmetric 1,3-DC of imino esters with vinyl sulfones was reported by Carretero and co-workers in 2006.^{27a} In 2008, our research group showed that an original copper/ClickFerrophos complex catalyst can be used to achieve higher enantioselectivity (Scheme 1-6).^{27b} Although the *exo*-adducts were obtained with high diastereoselectivity in both reports, Wang and co-workers reported in 2009 that their originally developed silver/TF-BiphamPhos gave the corresponding *endo*-adducts with high stereoselectivity.^{27c} This reaction also gave only *endo*-cycloadducts, even when copper salts were employed instead of silver acetate as the metal center. Therefore, its diastereoselectivity is thought to be controlled by the ligand, not the metal center.

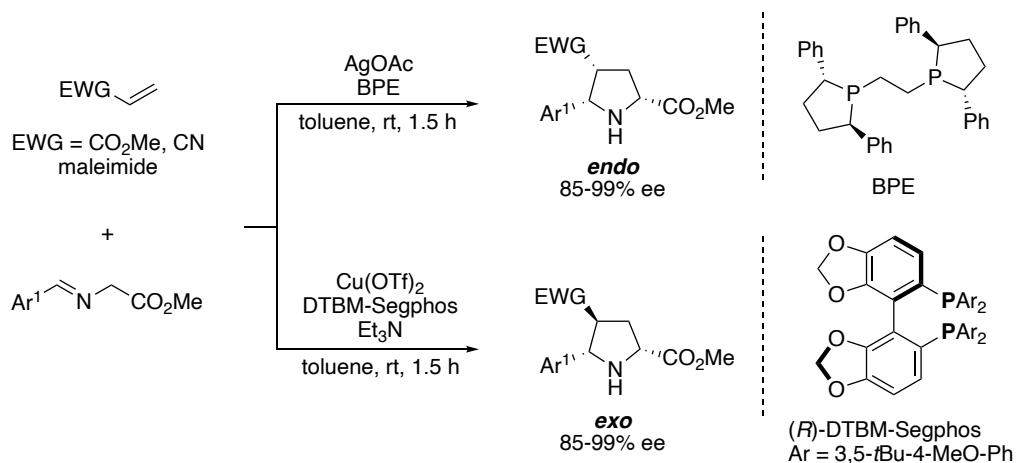

Scheme 1-6. *endo/exo*-Diastereodivergent reaction using vinyl sulfone.

In 2010, Carretero and co-workers reported an *endo/exo*-diastereodivergent copper-catalyzed asymmetric 1,3-DC of imino esters with β -sulfonylenones (Scheme 1-7).²⁸ Two regioisomers could be generated because the activated alkene used here has two types of electron-withdrawing groups, an acetyl group and a sulfonyl group. However, the pyrrolidines with the acetyl group substituted at the 4-position were obtained regioselectively. The diastereoselectivity was controlled by substituents on the

phosphorus atom of the chiral ligand Segphos. When the phenyl group substituted Segphos was employed, the *endo*-adducts were the major diastereomers with high enantioselectivity. DTBM-Segphos, which has bulky and electron-rich substituents, was found to give *exo*-adducts diastereo- and enantioselectively.

Scheme 1-7. *endo/exo*-Diastereodivergent synthesis using β -sulfonylenones.

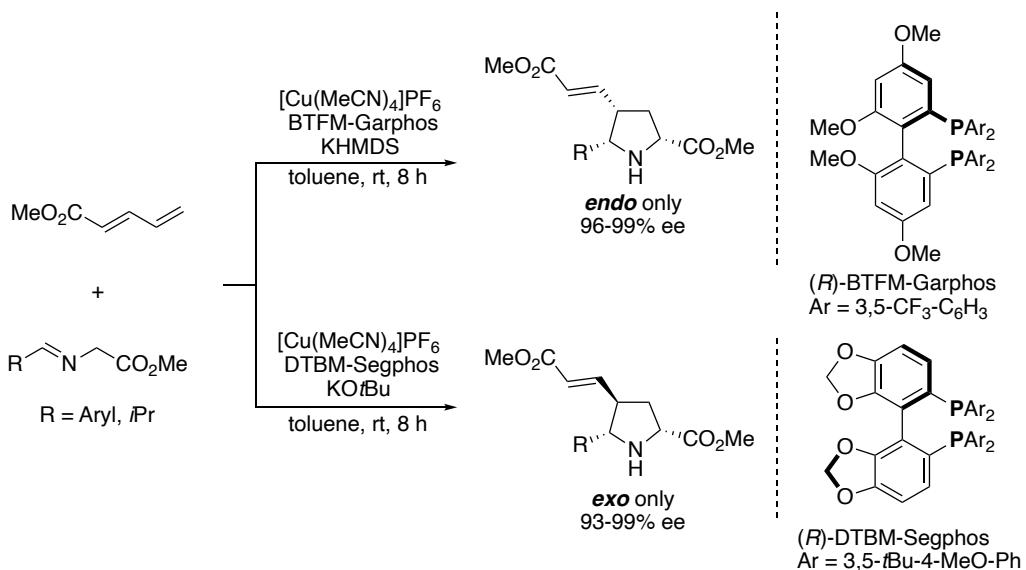

Scheme 1-8. Diastereodivergent synthesis controlled by silver and copper complex catalysts.

In 2012, Martín and co-workers developed an *endo/exo*-diastereodivergent reaction of imino esters with activated olefins such as acrylate, acrylonitrile, and maleimide.²⁹ The proper choice of silver or copper complex catalyst enabled the control of

diastereoselectivity (Scheme 1-8). This report is a typical example of the tendency to use silver complexes to give *endo*-adducts and copper complexes to give *exo*-adducts. Specifically, the use of silver acetate and the chiral ligand BPE gave *endo*-adducts enantioselectively, while the corresponding *exo*-adducts were obtained by using the copper Cu(OTf)₂/DTBM-Segphos complex.

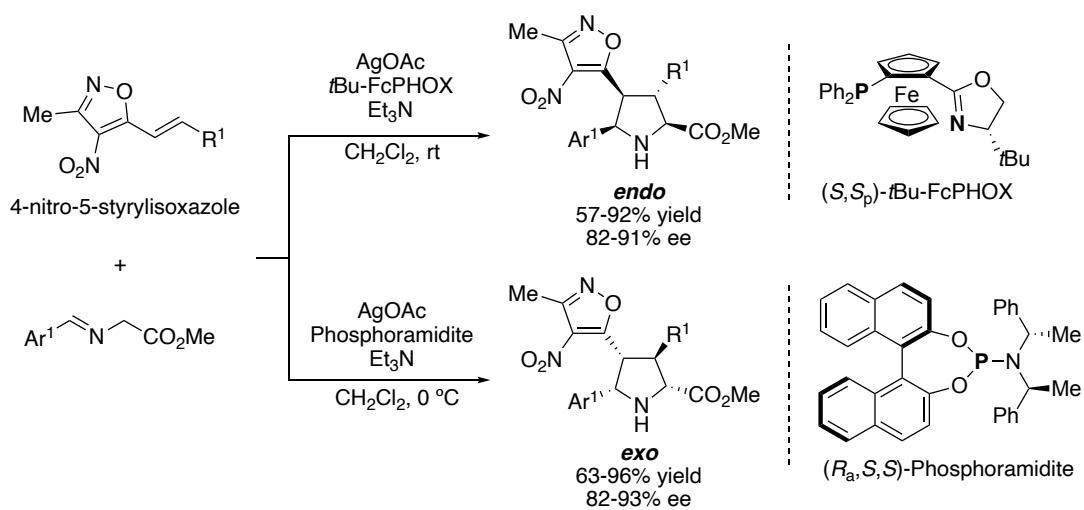

In 2015, Carretero and co-workers achieved *endo/exo*-diastereodivergent synthesis in the asymmetric 1,3-DC using 1,3-conjugated dienes as the activated olefins (Scheme 1-9).³⁰ In this reaction, regioselectivity is controlled under the standard conditions and the cycloaddition reaction takes place at the γ,δ -double bond of the conjugated diene. The *endo*-adducts were selectively obtained by using the biphenyl type of axially chiral diphosphine ligand BTFM-Garphos, while *exo*-adducts were produced under conditions using the DTBM-Segphos ligand. Namely, the diastereoselectivity could be completely reversed by the proper choice of the chiral ligand.

Scheme 1-9. Ligand-controlled diastereodivergent synthesis using 1,3-conjugated dienes.

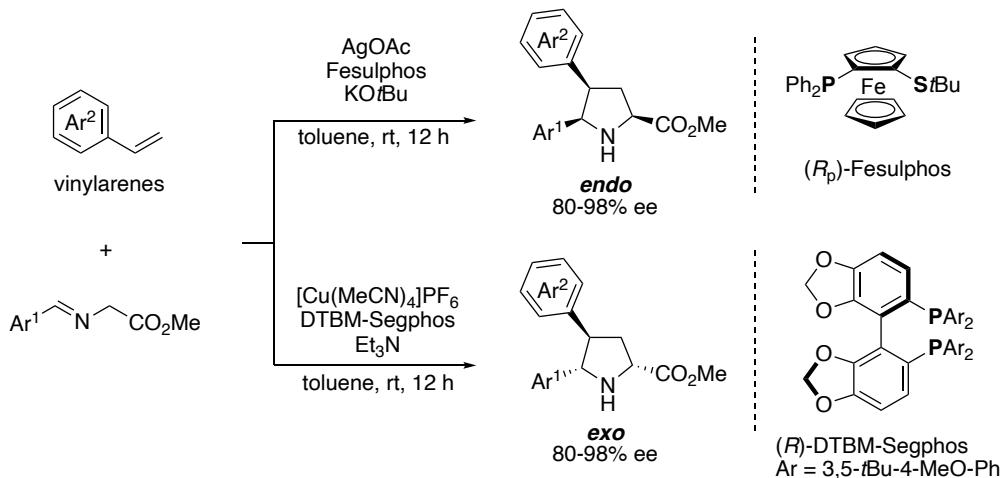

The following year, Wang and co-workers reported the silver-catalyzed *endo/exo*-diastereodivergent reaction of imino esters with nitro isoxazoles (Scheme 1-10).^{31a} The silver/tBu-FcPHOX complex catalyzed this reaction efficiently and gave the corresponding *endo*-cycloadducts in a highly enantioselective manner. On the other hand,

the reaction proceeded with *exo*-diastereoselectivities when a monodentate phosphoramidite ligand was applied to the silver-catalyzed condition. When our original Ag/TCF complex catalyst was used in this asymmetric cycloaddition, the *endo*-diastereomer was produced with high enantioselectivity.^{31b}

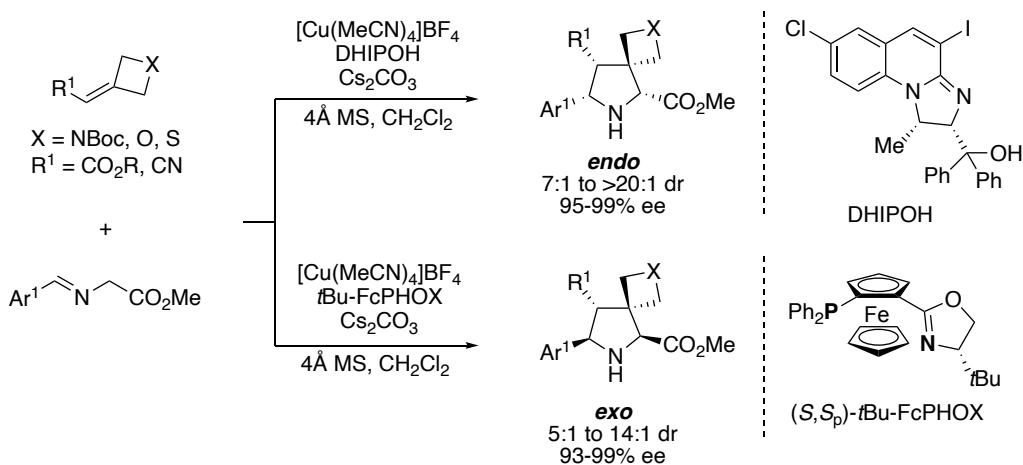

Scheme 1-10. Silver-catalyzed diastereodivergent synthesis in reaction of nitro-substituted isoxazoles.

In 2016, the diastereodivergent synthesis of the asymmetric 1,3-DC using vinyl arenes with nitro groups as active alkenes was reported by Carretero and co-workers (Scheme 1-11).³² The *endo/exo*-diastereoselectivity of the reaction was controlled by the silver and copper complex catalysts, respectively. In other words, the silver/Fesulphos complexes mainly gave *endo*-adducts enantioselectively, while the copper/DTBM-Segphos complexes gave only *exo*-adducts. In addition, it was shown that vinyl heteroarenes with pyridyl, quinolyl, or thiazole moieties could be used in the reaction. The reaction analysis based on theoretical chemical calculations revealed that the electron-withdrawing group attached to the aromatic substituent of the olefins greatly reduced the activation energy.

Scheme 1-11. *endo/exo*-Diastereodivergent reaction of imino esters with nitro-substituted vinyl arenes.

In 2019, Deng and co-workers achieved the diastereodivergent synthesis of spiropyrrolidines via copper complex-catalyzed asymmetric 1,3-DC reactions of imino esters with four-membered exocyclic olefins (Scheme 1-12).³³ The *endo/exo*-diastereoselectivity could be controlled by using an appropriate chiral ligand under the copper-catalyzed condition. Specifically, the *endo*-adducts were enantioselectively given when their originally developed N, O-ligand (DHIPOH) was used, and the *exo*-adducts were given as the major diastereomer when *t*Bu-FcPHOX was employed.

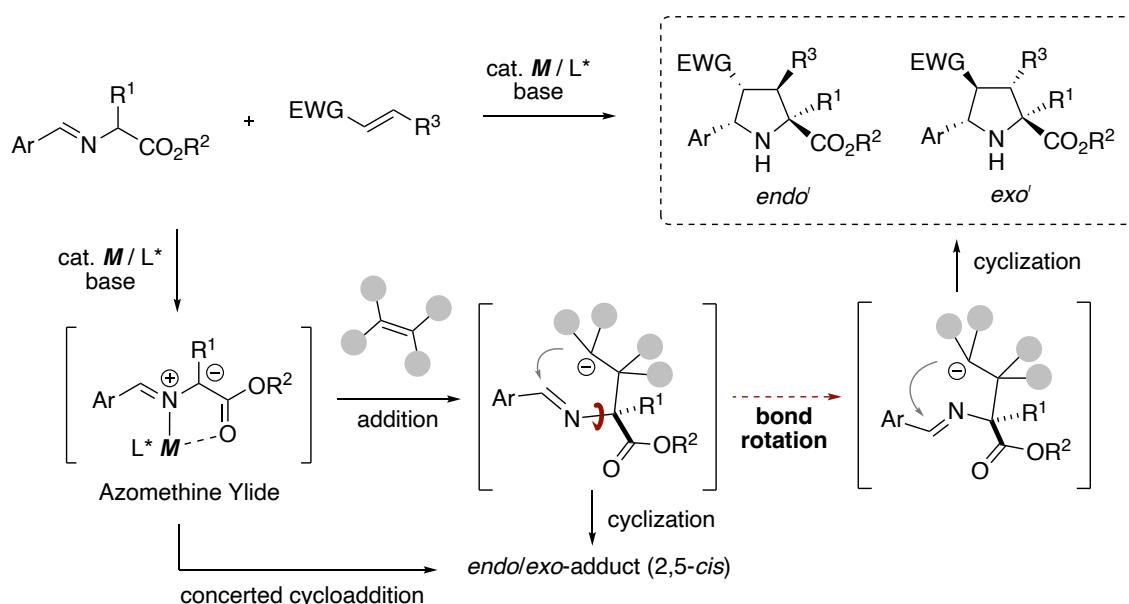

Scheme 1-12. Diastereodivergent synthesis of spiropyrrolidines using four-membered exocyclic olefins.

Sansano and co-workers reported studies on the relationship between *endo/exo*-diastereoselectivity and several dipolarophiles in the reaction using P, P-type chiral ligand Segphos in 2019.³⁴ P, P-Type ligand Segphos usually coordinates in a bidentate fashion to a metal center such as copper and silver to generate the corresponding azomethine ylides, which smoothly react with dipolarophiles. In this case, the dipolarophile does not interact with the metal center, and *exo*-diastereomers are produced. On the other hand, some reactions using the same type of P, P-ligand, DM-Segphos, produce *endo*-diastereomers. This indicates that the *endo*-selective reaction proceeds with the interaction of the metal center and the dipolarophile; DM-Segphos might have behaved as a monodentate ligand. Indeed, DFT calculations revealed that the transition state for *endo*-adducts was more favorable than that for *exo*-adducts in the reaction using DM-Segphos.

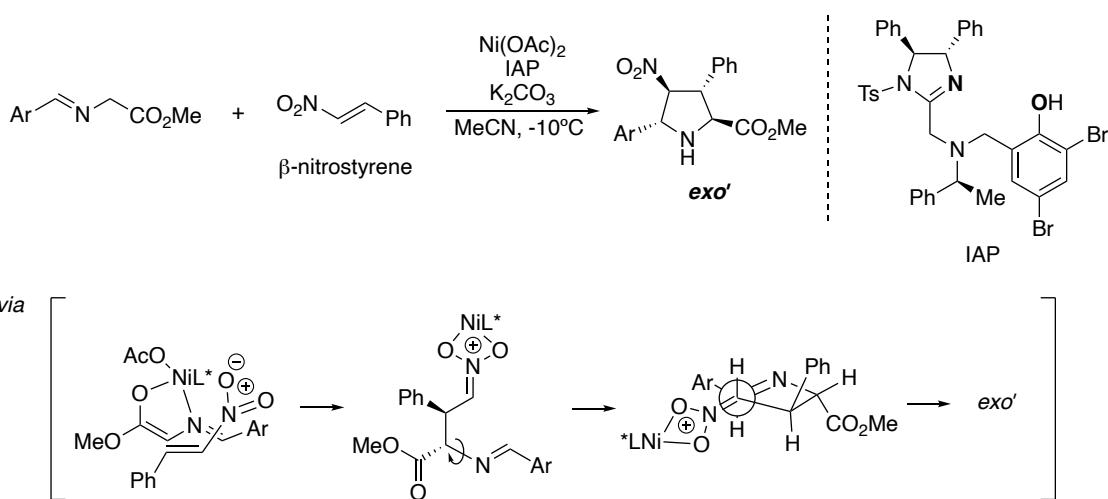

1–3–3. 2,5–*cis/trans*–Diastereodivergent Synthesis Using Imino Esters

As described above, *endo/exo*-diastereodivergent synthesis of pyrrolidine derivatives using asymmetric 1,3-DC has been reported, and numerous methodologies such as metal- and/or ligand-controlled strategies have been developed. However, methodologies for the diastereodivergent syntheses of 2,5-*cis* and 2,5-*trans* adducts (*endo'/exo'*) have been limited to a few examples.^{12,29} This may be because the 2,5-*trans* adducts are mechanistically difficult stereoisomers to form when using *cis*-type azomethine ylides generated by imino esters with a metal complex catalyst (Scheme 1–13). The cycloaddition reaction generally gives the 2,5-*cis* adducts from *cis*-type azomethine ylides by a concerted mechanism that forms two bonds almost simultaneously and a similar stepwise cycloaddition. In contrast, if the reaction is via stepwise cycloaddition, in which the C–N bond is rotated during the reaction to switch the reaction face of the imine, the 2,5-*trans* adducts can be produced. However, few methods have been established that can lead to this unfavorable reaction pathway, and it is difficult to switch the pathways precisely. Therefore, the 2,5-*cis/trans*-diastereodivergent synthesis has been reported in only a few cases.

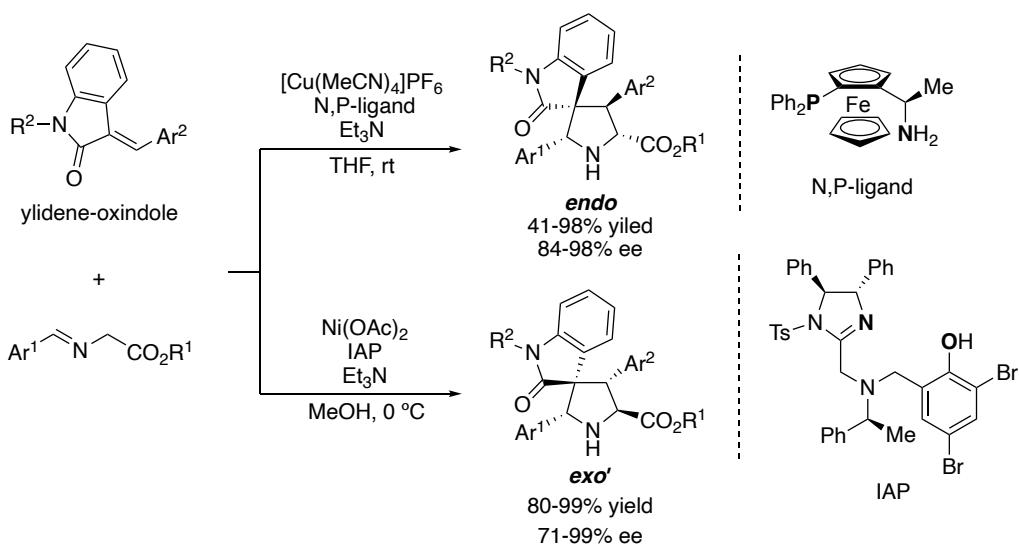

Scheme 1-13. Stepwise addition/cyclization with bond rotation pathway to afford 2,5-*trans* adducts.

In a pioneering study in 2010, Arai and co-workers reported the first synthesis of *exo'*-adducts in the asymmetric 1,3-DC reaction of imino esters with nitro olefins (Scheme 1-14).^{35a,c} In this reaction, which usually proceeds with 2,5-*cis* diastereoselectivity, the diastereoselectivity was switched to the rare 2,5-*trans* when their originally developed nickel/imidazole-aminophenol (IAP) catalyst was used. The mechanism is thought to be the above-described stepwise cycloaddition with bond rotation (Scheme 1-13), rather than the concerted 1,3-DC that is common in this reaction. First, an intermolecular anti-Michael addition reaction takes place from the azomethine ylide generated by the imino ester with a nickel complex catalyst to the nitro olefin. The interaction between the olefin-derived nitro group and the nickel center controls the stereochemistry at the 2- and 3-positions of the forming pyrrolidine ring. The nickel catalyst immediately flips from the imino ester moiety to the anionic nitro group to produce an intermediate. Subsequently, the imino ester-derived C–N bond is rotated and an intramolecular Mannich reaction takes place to give the *exo'*-adducts. If the Mannich reaction occurs without the rotation of the C–N bond after the formation of the intermediate, the *endo*-adducts are generated.

Scheme 1-14. *exo'*-Selective synthesis by nickel complex-catalyzed asymmetric 1,3-DC of imino esters with nitro olefins.

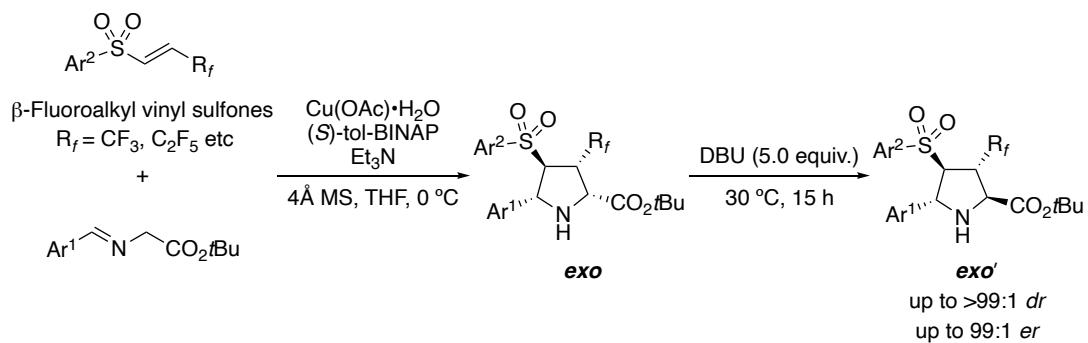

Scheme 1-15. 2,5-*cis/trans* Diastereodivergent synthesis of indole-based spiropyrrolidines by catalyst-controlled strategy.

The catalytic asymmetric 1,3-DC of imino esters with ylidene-oxyindoless was first reported by Waldmann and co-workers in 2010, who demonstrated that the *endo*-adducts were obtained with high stereoselectivity when using a copper/ferrocenyl amine complex (Scheme 1-15).^{36a} Wang and co-workers had shown that this reaction proceeds with the same *endo*-diastereo- and enantioselectivity when silver complexes were employed.^{36b} In

contrast, the Ni/IAP complex catalyst developed by Arai and co-workers catalyzed this reaction efficiently and exhibited high *exo'*-diastereoselectivity and enantioselectivity.^{35b} Thus, 2,5-*cis/trans* diastereodivergent synthesis of spiropyrrolidines, which includes the construction of a quaternary spiro carbon, has been achieved by a catalyst-controlled strategy.

The diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines can also be achieved by epimerization at the 2-position of the constructed pyrrolidine ring. The first epimerization strategy was developed by Huang and co-workers in 2019 (Scheme 1-16).^{37a} Initially, the *exo*-adducts were synthesized enantioselectively by using a copper/tol-BINAP complex in the asymmetric 1,3-DC of imino esters with β-fluoro alkyl vinyl sulfones. When DBU, an organic base, acted upon the *exo*-adduct obtained here, the stereocenter at the 2-position of the *exo*-adduct was inverted to give the *exo'*-adducts. Namely, the 2,5-*trans* adducts, i.e., *exo'*-adducts, took advantage of the thermodynamic stability of the corresponding *exo*-adducts. This epimerization strategy was successfully extended to the reaction of imino esters with α-fluoro-α,β-allyl ketones.^{37b} Specifically, in the case of Cu/tol-BINAP complexes, the *exo*-selective asymmetric cycloaddition with imino esters and α-fluoro α,β-allyl ketones occurred, yielding pyrrolidines which had fluorine and carbonyl groups substituted at the 4-position. The 2-epimerization of pyrrolidines that have tetrasubstituted carbons at the 4-position was also promoted by the action of DBU, and the *exo/exo'*-diastereodivergent synthesis was accomplished.

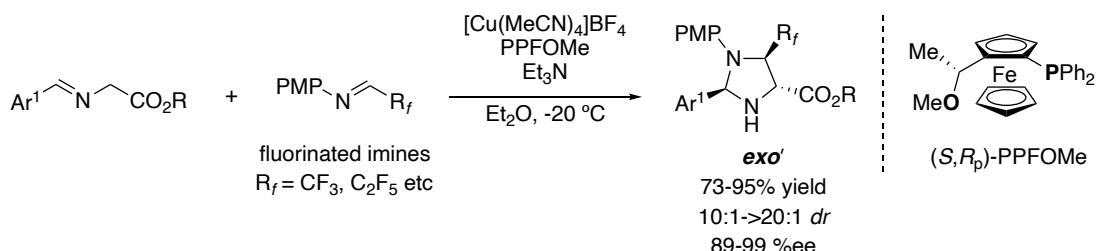

Scheme 1-16. 2,5-*cis* Selective ring formation and subsequent 2-epimerization strategy.

In summary, only two methodologies have been proposed for *2,5-cis/trans* diastereodivergent synthesis in the catalytic asymmetric 1,3-DC using imino esters. One method uses a nickel complex catalyst developed by Arai's group³⁵ and the other uses the epimerization of the initially formed *2,5-cis* adducts achieved by Huang's group.³⁷ Examples of the *2,5-cis/trans* stereodivergent synthesis are limited compared to the *endo/exo*-diastereodivergent synthesis using various methodologies. In other words, although many methodologies have been proposed for stereodivergent synthesis, it is still difficult to achieve *2,5-cis/trans* diastereodivergent synthesis by existing methodologies such as copper- and silver-catalyzed conditions. Therefore, a new and novel strategy is desired for the *2,5-cis/trans* diastereodivergent synthesis using azomethine ylides.

1-3-4. *2,5-trans* Selective Cycloaddition Using Azomethine Ylides

Examples of asymmetric synthesis of both *2,5-cis* and *trans* diastereomers by this reaction are described above. In addition, some reactions are known in which only the *2,5-trans* adduct is selectively obtained, but these are not stereodivergent syntheses. Although it is difficult to decipher the trend for the *2,5-trans* diastereoselectivity from these reactions, they are valuable and pioneering studies.³⁸

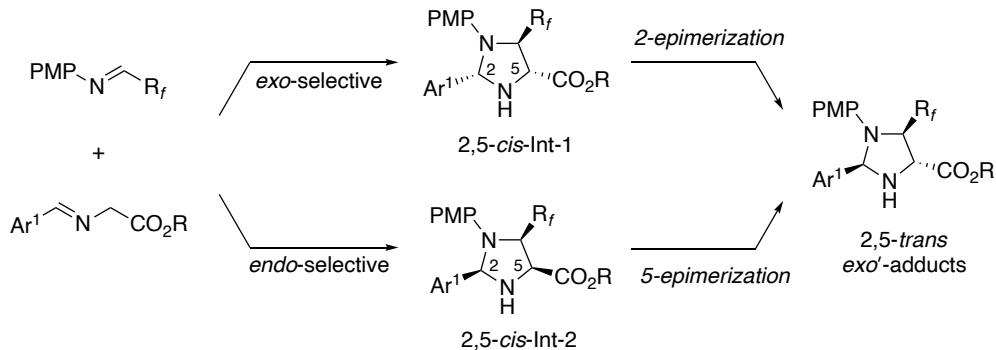

Scheme 1-17. *exo'*-Selective asymmetric 1,3-DC using fluorine-substituted imines.

In 2013, Wang and co-workers reported the asymmetric 1,3-DC reaction of imino esters with fluorine-substituted imines, giving chiral imidazolidines (Scheme 1-17).^{39a} The reaction was found to give the corresponding *exo'*-adducts enantioselectively when the Cu/PPFOMe complex was employed. Although several metals, ligands, and reaction conditions were screened, the diastereoselectivity was never completely switched to *2,5-*

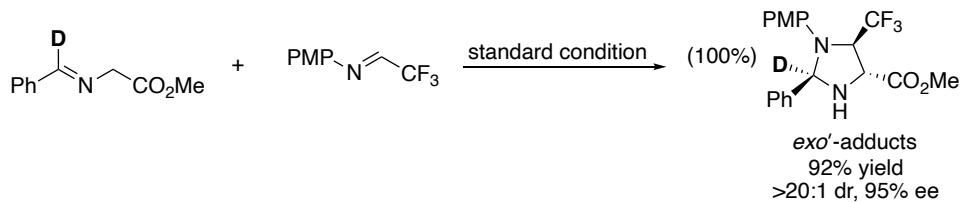

cis. This suggests that the 2,5-*trans* diastereoselectivity may depend highly on the fluorine-substituted imines rather than on the catalyst and conditions.

In 2018, Wang and co-workers reported a study on the mechanism for the rare 2,5-*trans* selectivity observed in the reaction using fluorine-substituted imines.^{39b} First, a reaction mechanism via the epimerization of 2,5-*cis* adducts commonly obtained was considered (Scheme 1-18a). One possible pathway is that the *exo*-selective cycloaddition gives the intermediate 2,5-*cis*-Int-1, which is converted to the corresponding 2,5-*trans* adduct by epimerization of the 2-position. Another route is the *endo*-selective cycloaddition reaction which gives the intermediate 2,5-*cis*-Int-2 and the subsequent epimerization of its 5-position. To validate these possible reaction pathways, corresponding control experiments were carried out. First, the (3+2) cycloaddition reaction was performed using an imino ester whose imine moiety was deuterated as the azomethine ylide precursor to verify whether the 2-epimerization occurs (Scheme 1-18b). The optimal conditions in the presence of methanol as the solvent gave the corresponding 2,5-*trans* adducts with high enantioselectivity. A deuteration ratio of >99% suggested that the 2-epimerization did not occur *in situ*. Next, the reaction pathway involving the epimerization at the 5-position was investigated by using an alanine-derived imino ester in which the hydrogen atom at the α -position was replaced by a methyl group (Scheme 1-18c). If the 2,5-*cis* adduct is formed temporarily as the intermediate, the 2,5-*trans* adduct is never obtained as a product because the tetrasubstituted carbon at the 5-position cannot epimerize. In other words, the *endo*-adduct should be obtained as the product when the common *endo*-selective (3+2) cycloaddition using α -methyl substituted azomethine ylides takes place. However, the *exo'*-adduct was obtained, and its stereochemistry was confirmed by X-ray crystallographic analysis. Therefore, it was clarified that *endo*-selective cycloaddition and subsequent epimerization at the 5-position did not occur.

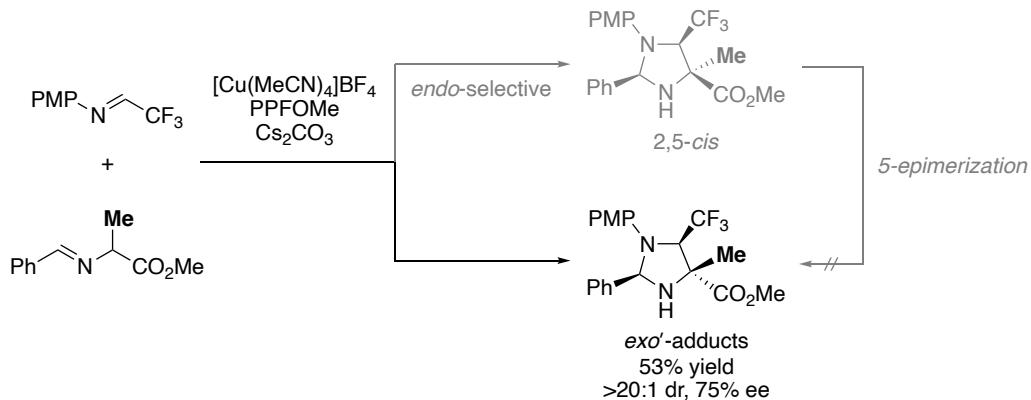

(a) Possible epimerization pathways for the *exo'*-adducts

(b) Investigation of 2-epimerization by using deuterium-labeled imino ester

(c) Investigation of 5-epimerization by using alanine-derived imino ester

Scheme 1-18. 2,5-*cis* Selective cycloaddition and subsequent epimerization pathways.

These control experiments suggest that the 2,5-*trans* diastereoselectivity observed in this reaction is due to a stepwise (3+2) cycloaddition with bond rotation (Figure 1-5). The Mannich reaction initially occurs from azomethine ylide **A** generated by imino esters and the copper catalyst to the *re*-face of fluorine-substituted imines. The stereochemistry is controlled by the Gauche conformation, giving the amphoteric ion intermediate **B**. Next, the copper catalyst coordinating the imino ester moiety switches its coordination to N-PMP to give intermediate **C**, which has a six-membered ring chair configuration. The

C–N bond rotation then takes place to give conformation **D**, and intramolecular cyclization to the *re*-face of the imine moiety results in the formation of the 2,5-*trans* adduct. The chair-configuration intermediate **C** has a hydrogen atom and a methoxy group in the 1,3-diaxial positions, which may contribute to the stabilization of this intermediate. When the hydrogen atom was replaced with an ethyl ester, this intermediate would not be stabilized by 1,3-diaxial interactions and the 2,5-*trans* adduct would not be formed. To test this hypothesis, the 1,3-DC reaction of imino esters with α -CF₃-ketimine esters was investigated, and it was found that *endo*-adducts, not *exo'*-adducts, were obtained. Namely, the six-membered ring intermediate **C** is not formed, and the second cyclization reaction is considered to have immediately occurred after the first bond formation. These results indicate that stabilization of the intermediate plays a key role in the 2,5-*trans* diastereoselectivity; the 1,3-diaxial interaction in the six-membered chair conformation has a significant effect on the rare diastereoselectivity of this imidazolidine formation.

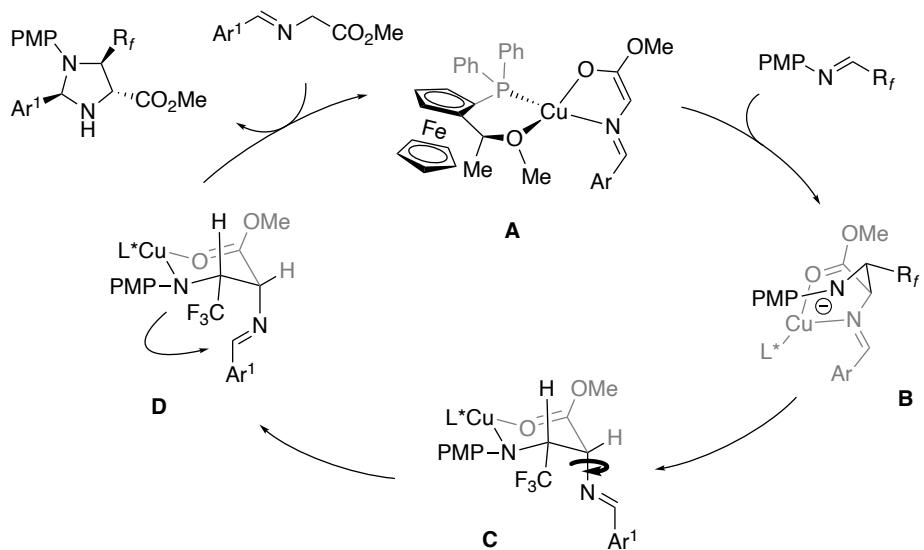

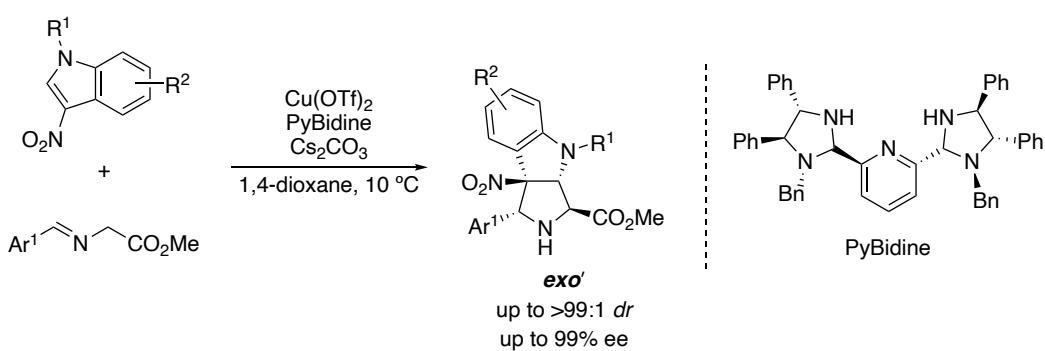

Figure 1-5. Proposed mechanism for the 2,5-*trans* diastereoselective imidazolidine formation by the asymmetric 1,3-DC of imino esters.

Having performed pioneering work on the 2,5-*cis/trans* diastereodivergent synthesis of imino esters by nickel complex catalysts, Arai and co-workers developed the copper-catalyzed asymmetric 1,3-DC reaction of imino esters with nitro indoles in 2014

(Scheme 1-19).⁴⁰ This report is the first example of dearomatic asymmetric cycloaddition reactions using indole-derived activated olefins, which had previously been limited as nucleophiles. Interestingly, the reaction was catalyzed by the copper/bis(imidazolidine)pyridine (PyBidine) complex to give the corresponding *exo'*-adducts with high diastereo- and enantioselectivity. Also, the nickel complex catalysts that had been effective for *exo'*-selective reactions were not suitable for controlling the diastereoselectivity. On the other hand, copper/PyBidine complexes are known to give *endo*-adducts stereoselectively in the asymmetric 1,3-DC reaction of imino esters with nitro styrenes.⁴¹ Therefore, this rare diastereoselectivity would be highly dependent on the copper catalyst used and the indole-based nitro olefins.

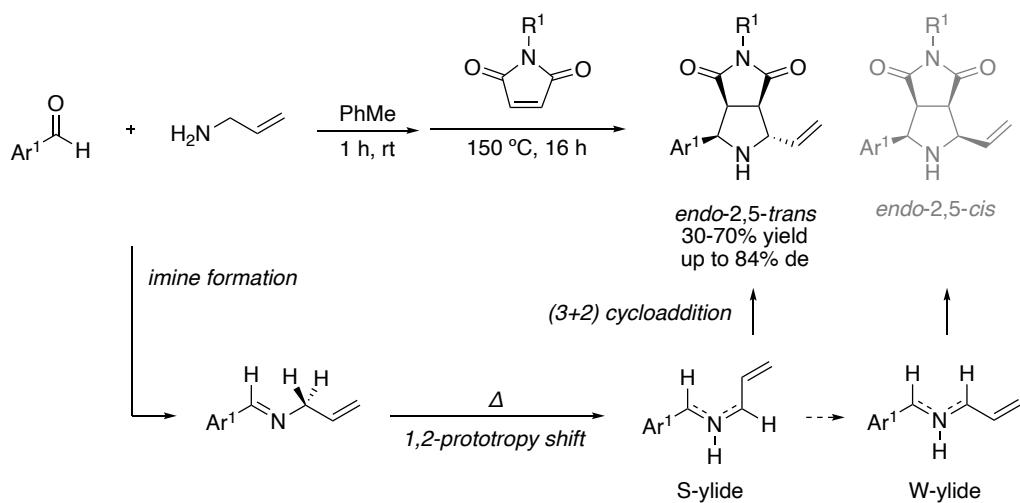

Scheme 1-19. *exo'*-Selective synthesis by asymmetric 1,3-DC using nitro-functionalized electron-deficient indoles.

In recent years, it has been reported that heat-generated azomethine ylides give 2,5-*trans* adducts, which can be considered a classical method. The azomethine ylides derived from imino esters change their conformation during the middle of the cycloaddition, where some azomethine ylides are converted to a favorable conformation for the 2,5-*trans* adducts before the start of bond formation.⁴² However, this method is not suitable for stereodivergent synthesis, including enantiomers, because it requires heating for conformational control.

For example, in 2018, Sansano and co-workers reported that the three-component coupling of an aldehyde, allylamine, and maleimide proceeds with 2,5-*trans*

diastereoselectivity (Scheme 1-20).^{43a} In this reaction, imine formation first takes place, and the resulting imine undergoes a 1,2-hydrogen transfer reaction to generate S-ylides. The generated S-ylide reacts with maleimide which is the dipolarophile to give the 2,5-*trans* pyrrolidines diastereoselectively. If the conformational W-ylide isomers react with the activated olefins, the 2,5-*cis* substituted pyrrolidines are formed. The reaction analysis using DFT calculations indicated the highest activation energy in the transition state of the 1,2-hydrogen transfer reaction, suggesting that it is the rate-limiting step. In addition, the activation energy for the isomerization of S-ylides to W-ylides was estimated to be sufficiently larger than that for the (3+2) cycloaddition reaction. Thus, the cycloaddition of S-ylides with maleimide proceeds preferentially over the isomerization of S-ylides to W-ylides. However, the isomerization could still take place because it has a lower activation energy than the 1,2-hydrogen transfer reaction. In addition, the W-ylide is slightly more thermodynamically stable. These facts suggest that controlling the 2,5-*cis/trans* diastereoselectivity completely would be difficult. It was shown in 2023 that the 2,5-*trans* selectivity is improved by using the same 1,2-hydrogen transfer method when propargyl amine is used instead of allylamine.^{43b}

Scheme 1-20. 2,5-*trans* Selective (3+2) cycloaddition of azomethine ylides generated by the 1,2-hydrogen transfer reaction.

Aly and co-workers reported that azomethine ylides similar to S-ylides are generated not only when using aryl amines and propargyl amines as described above, but also when using amino methyl pyridines and amino acid esters, and that they can be used for the synthesis of 2,5-*trans* adducts.⁴⁴ In particular, when arylidene with an ester moiety and cyano group was applied as the activated alkene, the 2,5-*cis* adducts were kinetically formed and the 2,5-*trans* adducts were thermodynamically obtained. In addition, the kinetic product, the 2,5-*cis* cycloadduct, was readily converted to the 2,5-*trans* conformation under mild conditions. It has been thought that the reverse reaction of the 1,3-DC reaction takes place, in which the regenerated ylide is isomerized and the cycloaddition reaction occurs again.

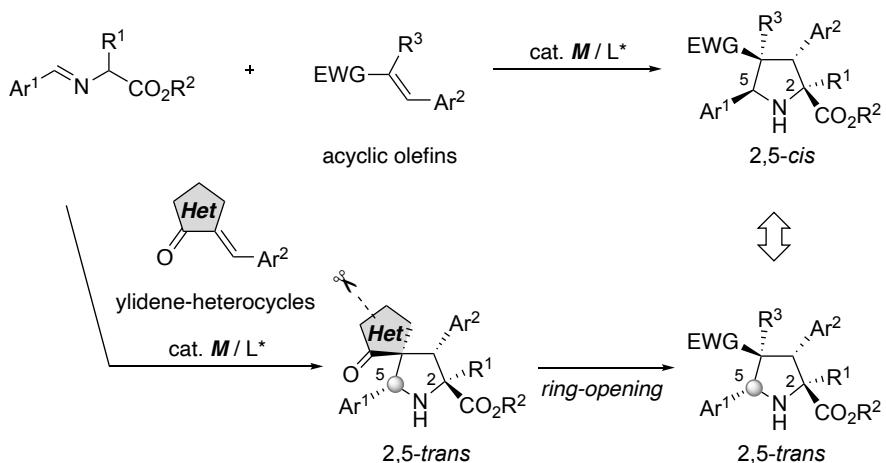

1–4. Outline of the Dissertation

As described in this chapter, despite the potential of both 2,5-*cis/trans* substituted pyrrolidines as biologically active molecules, few methods for efficient diastereodivergent preparation have been developed. Many diastereodivergent syntheses have been developed based on asymmetric 1,3-DC reactions of imino esters with activated olefins, which are efficient synthetic methods for chiral pyrrolidines. However, almost all have featured creating 2,5-*cis* configurations such as *endo/exo* adducts despite the development of many catalytic systems. Indeed, the 2,5-*cis/trans* divergent synthesis is limited to two methods involving epimerization of the 2,5-*cis* adducts found by Huang and co-workers³⁷ and the pioneering work using nickel complexes developed by Arai and co-workers.³⁵ This is due to the fundamental difficulty in synthesizing 2,5-*trans* adducts in the 1,3-DC using imino ester-derived *cis*-formed azomethine ylides. Synthesis of the 2,5-*trans* adducts requires a stepwise addition/cyclization with bond rotation, which is commonly unfavorable to the concerted pathway for giving the corresponding 2,5-*cis* adducts. Therefore, in this study, the author aimed to realize 2,5-*cis/trans* diastereodivergent synthesis using catalytic asymmetric 1,3-DC and to develop a new methodology for the 2,5-*trans* pyrrolidines.

In Chapter 2, the results are described for the asymmetric (3+2) cycloaddition of imino esters with α,β -unsaturated cyclic sulfonic esters. The cyclic sulfonic acid esters (sultones) had only been employed in thermal 1,3-DC reactions with nitrones and nitrile oxides, and their development for the stereoselective synthesis by catalytic reactions had not yet been explored. In this study, catalytic asymmetric (3+2) cycloadditions of imino esters with two types of sultones were investigated. The results showed that the copper complex catalyzed the reaction efficiently and the corresponding sultone-fused pyrrolidines were generated with high enantioselectivity for two types of sultones. Also, the reaction only gave the *exo*-diastereomers (2,5-*cis* adducts).

The research on asymmetric (3+2) cycloaddition of imino esters with ylidene-2,3-dioxopyrrolidines is described in Chapter 3. While previous studies have shown that the common 2,5-*cis* selective reaction proceeded when ylidene-oxindole or ylidene-succinimide was used, this reaction gave the rare *exo'*-adducts (2,5-*trans*). Furthermore, it was found that the corresponding spiropyrrolidines were produced with high enantioselectivity when our original silver/TCF complex catalyst was used. Control experiments suggested that a stepwise addition/cyclization with a bond rotation pathway is responsible for the rare 2,5-*trans* diastereoselectivity, not the 2,5-*cis* selective cycloaddition and subsequent epimerization pathway.

Since it was found that the reaction substrate (activated olefins) frequently governs the 2,5-*cis/trans*-diastereoselectivity, the author envisioned that the formal diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines could be realized by using different types of activated olefins (Scheme 1-21). The (3+2) cycloaddition of imino esters with acyclic olefins gave the common 2,5-*cis* adducts. In contrast, the (3+2) cycloaddition with ylidene-heterocycles which are easy to ring-open gave the corresponding spiropyrrolidines with 2,5-*trans* diastereoselectivity. Subsequent ring-opening of the heterocyclic moiety led to the 2,5-*trans* pyrrolidines with common substituents. Therefore, the author hypothesized that a series of these reactions could be a new diastereodivergent method to prepare 2,5-*cis/trans* pyrrolidines.

Scheme 1-21. 2,5-*cis/trans* Diastereodivergent synthesis using ylidene-heterocycles.

Based on the above hypothesis, the asymmetric (3+2) cycloaddition of imino lactones with ylidene-isoxazolones and the formal diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines are described in Chapter 4. The desired cycloaddition using ylidene-isoxazolones⁴¹ was efficiently catalyzed by a chiral silver complex, giving the 2,5-*trans* spiropyrrolidines with high enantioselectivity. In addition, the isoxazolone ring was smoothly converted to a ketone group by the Pd/C catalyzed reduction of the weak N–O bond. In contrast, the silver complex-catalyzed asymmetric 1,3-DC of imino lactones with α,β-unsaturated ketones gave the corresponding 2,5-*cis* pyrrolidines with high enantioselectivity. Thus, the formal diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines was achieved using the isoxazolone ring as a ketone equivalent.

The 2,5-*trans* selective cycloaddition reaction of imino lactones with ylidene-pyrazolones is described in Chapter 5. Pyrazolone is a heterocyclic structure that is similar to the isoxazolone ring described in Chapter 4. The reaction is known to proceed with 2,5-*trans* diastereoselectivity when the organocatalysts are used, but it was found to exhibit similar diastereoselectivity when using metal complex catalysts. Also, the reaction resulted in high enantioselectivity when a common chiral copper complex catalyst was used.

Chapter 6 is a summary of the entire study.

Chapter 2

Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Esters with α,β -Unsaturated Sultones

2–1. Introduction

The asymmetric 1,3-DC of azomethine ylides generated by imino esters and a chiral metal complex catalyst is an efficient method for constructing chiral pyrrolidine rings.¹ Directed toward establishing a new synthetic method for pyrrolidine-containing biologically active compounds,^{2,3} many types of catalyst systems have been reported to control the stereochemistry. In this process, various activated olefins have been employed that have been found to be widely applicable to this reaction. In particular, our research groups have adopted activated olefins bearing a heterocyclic moiety and developed a synthetic method for pyrrolidines containing another heterocycle by this asymmetric cycloaddition.⁴ For example, in 2018, we reported the catalytic asymmetric 1,3-DC of imino esters with benzo[*b*]thiophene-1,1-dioxides to produce sulfone-fused pyrrolidines with high stereoselectivity.^{4a}

As a heterocyclic compound that has potential bioactivity, the author focused on the sultone scaffold (cyclic sulfonic acid esters) which plays an important role in biologically active compounds.⁵ For example, some five- and six-membered sultone derivatives behave as inhibitors of human cytomegalovirus (HCMV), varicella zoster virus (VZV), human immunodeficiency virus (HIV), and bovine viral diarrhea-mucosal disease (BVDV) (Figure 2-1).⁶ Therefore, sultone-containing pyrrolidine compounds are attractive molecules in the field of drug discovery.

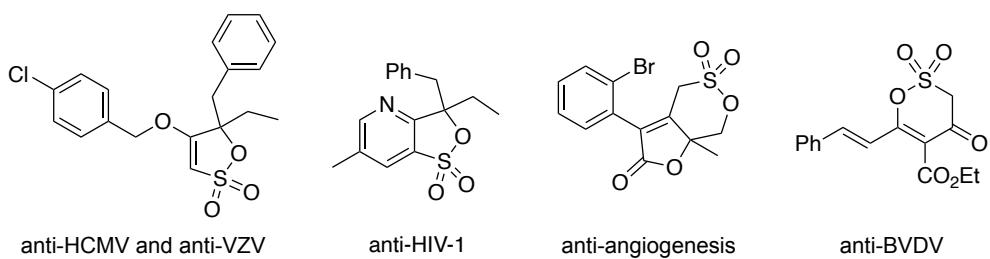

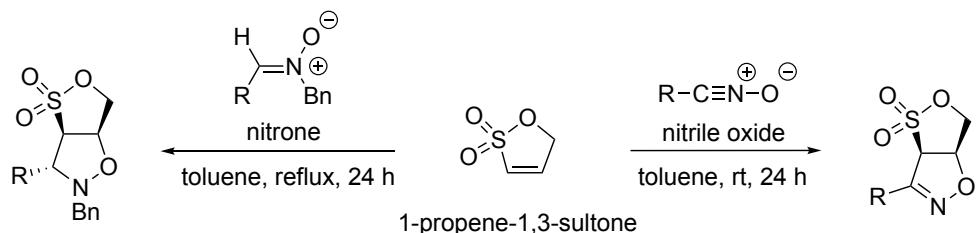

Figure 2-1. Example of biologically active compounds containing sultone moiety.

However, there are few synthetic methods for introducing the sultone moiety by stereoselective cycloaddition. The pioneering work for the synthesis of sultone-fused

compounds by the cycloaddition process was reported by Chan and co-workers in 1997.⁷ They revealed that 1-propene-1,3-sultone behaves as a good dienophile in the thermal Diels-Alder reaction. 1-Propene-1,3-sultone has also been applied in 1,3-DC reactions with nitrile oxides and nitrones and has been shown to work well as a dipolarophile (Figure 2-2a).⁸ However, these reports were conducted using thermal methods, and further studies for the development of catalytic asymmetric synthesis have not been explored.

Based on this background, the author envisioned a catalytic asymmetric 1,3-DC of imino esters with 1-propene-1,3-sultone to afford sulfone-fused pyrrolidines in an optically pure fashion (Figure 2-2b). Additionally, the author examined the reaction using sulfocoumarins (1,2-benzoxathiine-2,2-dioxides) as the dipolarophiles, which had not been applied as activated olefins in the Michael addition and cycloaddition reactions.⁹

(b) This work: asymmetric (3+2) cycloaddition of imino esters with α,β -unsaturated sultones

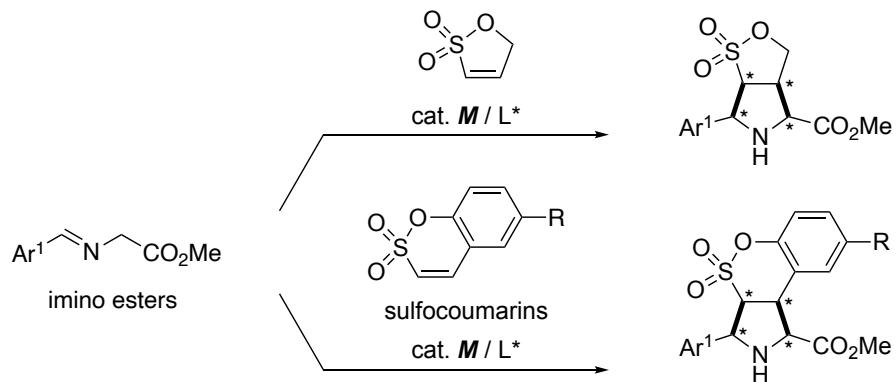

Figure 2-2. (a) previous report of the 1,3-DC of 1-propene-1,3-sultone and (b) this work.

2–2. Result and Discussion

The author first carried out the reaction of *p*-chloro phenyl substituted imino esters **1a** with 1-propene-1,3-sultone (**2**) in the presence of copper/PPh₃ catalyst (5 mol%), Et₃N (18 mol%), and molecular sieves in THF at room temperature (Table 2-1, entry 1). The reaction proceeded smoothly and quantitatively to produce the corresponding cycloadduct **3a** as a single diastereoisomer. The reaction in the absence of ligands resulted in a lower yield and diastereoselectivity, and no reaction proceeded without the use of metal salts (entries 2, 3). The reaction using silver acetate (AgOAc) as the metal salt afforded cycloadduct **3a** but with moderate yield (entry 4). Thus, these initial experiments indicated that the copper/phosphine complex is suitable for the stereoselective 1,3-DC.

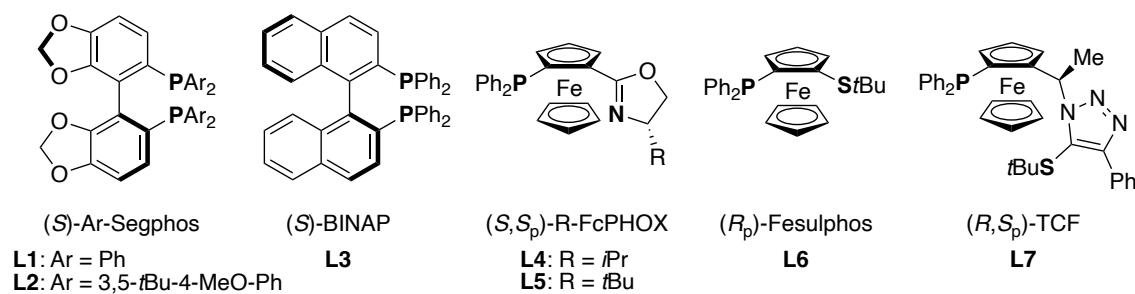

Figure 2-3. Chiral ligands employed in this study.

Next, the author considered the enantioselective reaction by applying some chiral phosphine ligands (Figure 2-3) to the reaction (Table 2-1, entries 5-11). Upon screening the representative axial asymmetric ligands **L1-3**, (S)-DTBM-Segphos **L2** gave the corresponding cycloadduct as a single diastereomer with excellent enantioselectivity (entry 6). FcPHOX **L4** and **L5** resulted in good to high enantioselectivity, but they were less effective than DTBM-Segphos **L2** (entries 7, 8). Ferrocene-based chiral ligands such as Fesulphos **L6** and ThioClickFerrophos **L7** (TCF) yielded the cycloadducts with low to moderate enantioselectivity (entries 10, 11). Other solvents were examined under conditions catalyzed by the copper/DTBM-Segphos **L2** complex (entries 12-14), and the enantioselectivity was improved while maintaining high yield using CH₂Cl₂. (entry 14).

Table 2-1. Initial experiment and optimization of the reaction conditions.^a

14	L2	CH ₂ Cl ₂	99	97

[a] Condition: **1a** (0.20 mmol), **2** (0.22 mmol), [Cu(MeCN)₄]BF₄ (0.010 mmol, 5.0 mol%), ligand (0.011 mmol, 5.5 mol%), 3 Å MS (100 mg), solvent (1 mL), rt, 16 h. The diastereomeric ratio was determined by crude ¹H NMR. [b] Isolated yield. [c] The enantiomeric excess was determined by chiral HPLC. [d] Et₃N (18 mol %) was added. [e] The diastereomeric ratio was 2:1. [f] Without [Cu(MeCN)₄]BF₄. [g] AgOAc was used instead of [Cu(MeCN)₄]BF₄.

The substrate scope of the asymmetric 1,3-DC of imino esters **1** with 1-propene-1,3-sultone (**2**) was investigated under the optimized conditions (Table 2-1, entry 14), and a variety of sulfone-fused pyrrolidines were obtained with excellent yield and enantioselectivity as single diastereoisomers. *para*-Bromo, fluoro, and strong electron-withdrawing groups substituted on the imino esters smoothly reacted with 1-propene-1,3-

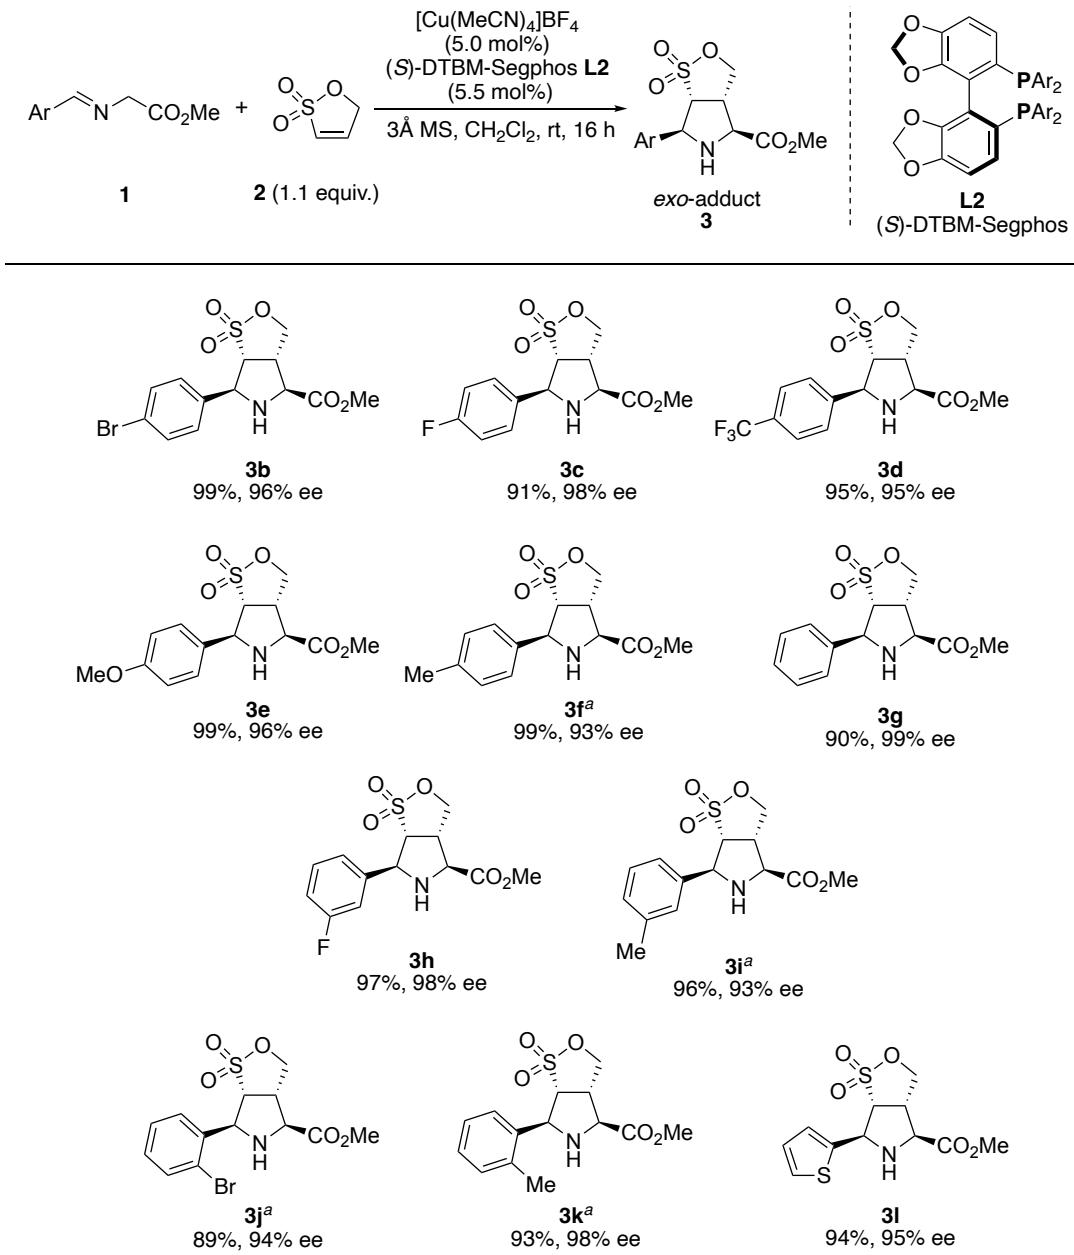

Figure 2-4. Scope of imino esters **1**.

sultone (**2**) to give the corresponding cycloadducts **3b-d**, respectively. The excellent yield and stereoselectivity were also maintained when imino esters bearing electron-donating groups, such as *p*-methoxy and methyl, and no substituents on the aryl groups were used in the reaction (**3e-g**). The reaction of imino esters bearing substituents at the *meta*- and *ortho*-positions also proceeded efficiently under the optimal conditions to give the corresponding cycloadducts **3h-3k** with high yield and enantioselectivity. In addition, a

heteroaryl substrate, such as 2-thiophene, could be applied to the reaction (**3I**). Thus, the electronic and steric nature of the aryl groups of imino esters had little effect on the yield of the products, diastereo- and enantioselectivity.

The author next attempted to apply the copper complex-catalyzed system to the reaction of imino esters **1** with sulfocoumarins **4**. As an initial experiment, the reaction of *p*-chloro substituted imino ester **1a** with sulfocoumarin **4a** was carried out in the presence of copper/DTBM-Segphos complex, Et₃N (10 mol%), and 3 Å MS (200 mg) in THF at room temperature for 16 h (Table 2-2, entry 1). As a result, the corresponding sulfocoumarin-fused cycloadduct was smoothly formed, however, the yield and stereoselectivity were not satisfactory compared to the reaction of 1-propene-1,3-sultone (**2**). The author screened several ligands under copper-catalyzed conditions to improve the yield and stereoselectivity (Table 2-2, entries 2-6). As shown in entry 4, using (*S*, *S_P*)-*t*Bu-FcPHOX **L5** was most effective in obtaining the product with high yield and enantioselectivity as a single diastereomer. Screening of solvents revealed that Et₂O was suitable for the asymmetric cycloaddition of imino ester **1a** with sulfocoumarins **4a** (entry 8). The reaction proceeded without the addition of a base, such as Et₃N, as well as when 1-propene-1,3-sultone (**2**) was used as the dipolarophile, and the product yield was slightly improved (entry 9). However, no reaction occurred when the reaction temperature was decreased to 0 °C in anticipation of improved enantioselectivity (entry 10). The AgOAc/*t*Bu-FcPHOX complex was unsuitable as a catalyst for the reaction, and the cycloadduct was hardly obtained (entry 11).

[a] Condition: **1a** (0.22 mmol), **4a** (0.20 mmol), $[\text{Cu}(\text{MeCN})_4]\text{BF}_4$ (5.0 mol%), ligand (5.5 mol%), Et_3N (10 mol%), 3 Å MS (200 mg), solvent (1 mL), rt, 16 h. The diastereomeric ratio was determined by crude ¹H NMR. [b] Isolated yield. [c] Determined by chiral HPLC. [d] The diastereomeric ratio was 8:1. [e] Conducted without Et_3N . [f] Conducted at 0 °C. [g] AgOAc was used as the metal salt.

The substrate scope was examined under the optimal conditions catalyzed by the copper/*t*Bu-FcPHOX complex (Table 2-2, entry 9), and a variety of sulfocoumarin-fused pyrrolidines were successfully obtained with high yield, diastereo- and enantioselectivity (Figure 2-5). Imino esters bearing bromo and methoxy groups on the phenyl ring at the *para*-position smoothly reacted with sulfocoumarin **4a** to afford the corresponding cycloadducts **5ba** and **5ea** efficiently. Even when the phenyl group had no substituent, high yield and stereoselectivity resulted (**5ga**, 86% yield, 90% ee). The products **5fa**, **5ia**, and **5ka** were respectively formed while maintaining high yield and stereoselectivity

when a methyl substituent was introduced at *para*-, *meta*-, and *ortho*- positions. A 2-thienyl substituent could also be applied to the reaction without loss of yield, diastereo- and enantioselectivity. Therefore, electronic and steric properties had little effect on the asymmetric cycloaddition as in the case of using 1-propene-1,3-sultone (**2**). A wide scope

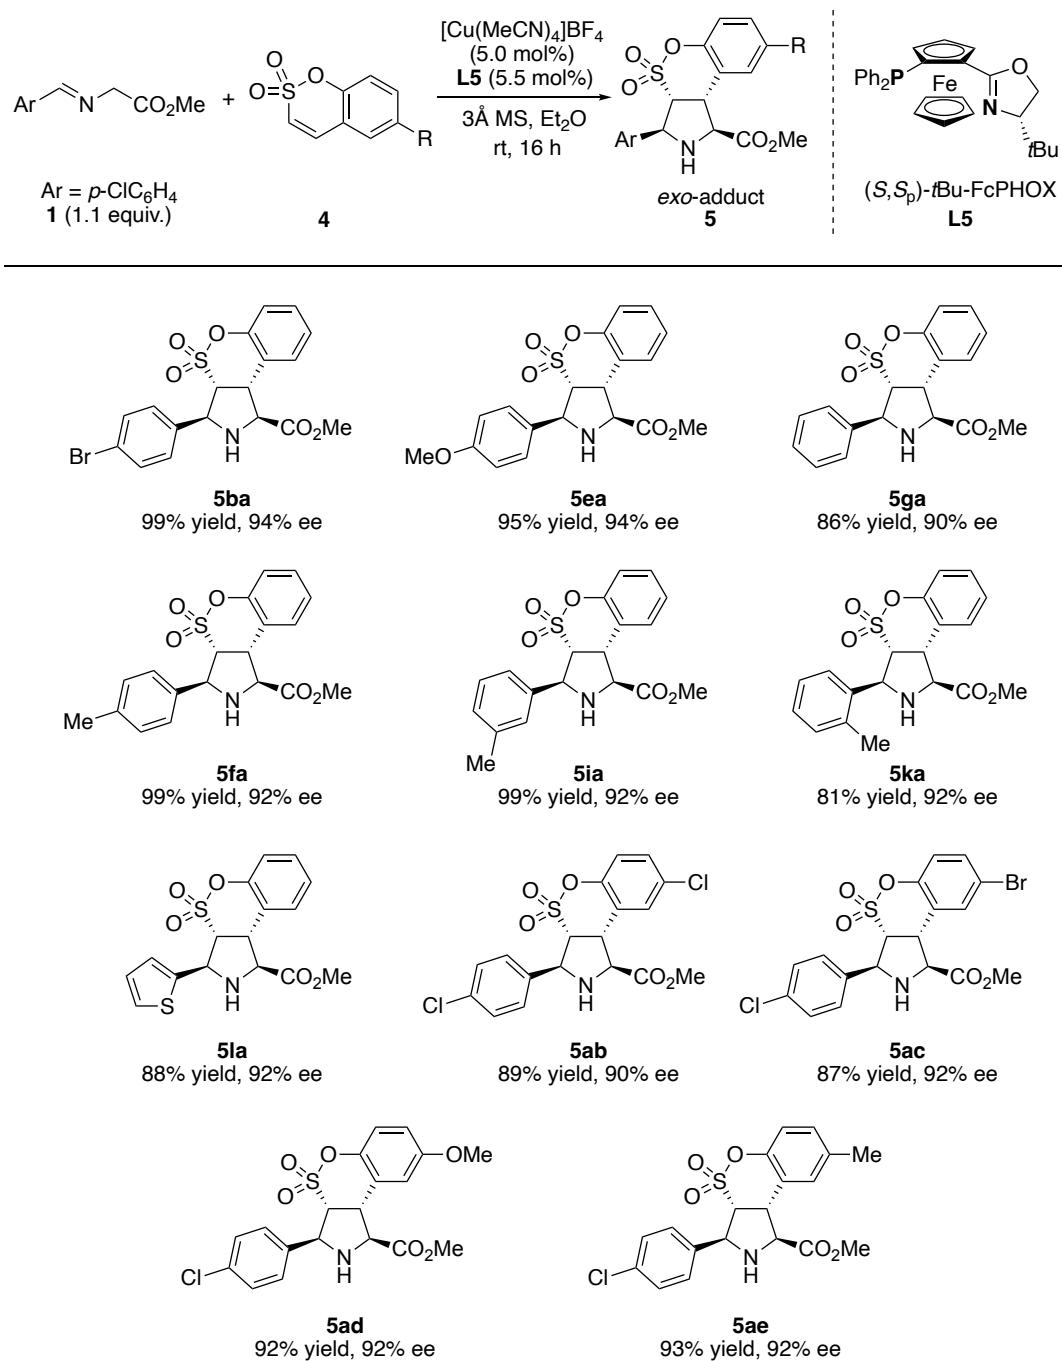

Figure 2-5. Substrate scope of imino ester **1** and sulfocoumarins **4**.

of sulfocoumarins was possible, and the enantioselective synthesis of some sulfocoumarin-fused pyrrolidines containing halogen, methoxy, and methyl substituents (**5ab-5ae**) was highly successful.

The stereochemistry of the sultone-fused pyrrolidines was determined by X-ray crystallographic analysis of the thiophene-substituted product *exo*-**3I** (Figure 2-6, left). The configuration could be classified as *exo* in that the sulfonyl group is *trans* to the thieryl group and the relative configuration of the methoxycarbonyl group with the thieryl group is *cis*. The *exo*-diastereoselectivity was similar to the previous reports using acyclic vinyl sulfone as the dipolarophile.¹⁰ The absolute configuration depended on the stereochemistry of the ligand, and several stereocenters were determined to be (3*aS*, 4*S*, 6*S*, 6*aS*). The relative and absolute configurations of the sulfocoumarin-fused pyrrolidine were determined by using a single crystal of the thieryl-substituted cycloadduct *exo*-**5la** (Figure 2-6, right). This analysis revealed that the cycloaddition using sulfocoumarin as the activated olefins also proceeded with *exo*-diastereoselectivity as in the case of 1-propene-1,3-sultone (**2**).

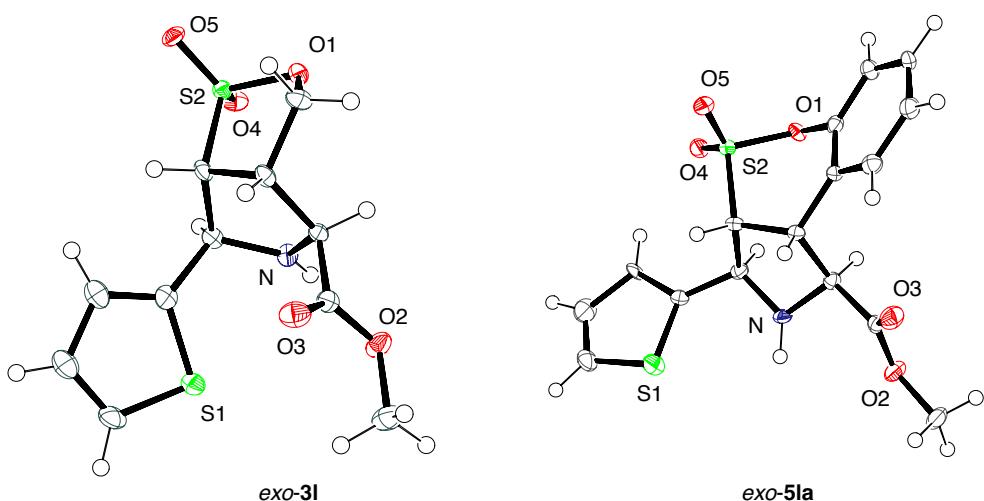

Figure 2-6. ORTEP drawing of the sultone-fused pyrrolidines.

2–3. Conclusion

The author has developed a copper complex-catalyzed asymmetric (3+2) cycloaddition of imino esters **1** with α,β -unsaturated cyclic sultones. The copper/DTBM-Segphos complex smoothly catalyzed the reaction using 1-propene-1,3-sultone (**2**) as the activated olefin to afford the *exo*-diastereomer with excellent enantioselectivity. In addition, the reaction of imino esters **1** with sulfocoumarins **4** proceeded with high yield and stereoselectivity when the copper/*t*Bu-FcPHOX complex was used as the catalyst. These reactions exhibited a wide range of substrate scopes and enabled the synthesis of sultone-fused pyrrolidines with various substituents.

2–4. Experimental Section

The following general information apply to chapter 2 to 5 unless otherwise noted.

General Information. The ^1H NMR spectra were obtained with a Varian Mercury 400 NMR spectrometer at 400 MHz. The ^{13}C NMR spectra were obtained with a Varian Mercury 400 NMR spectrometer 101 MHz. Unless otherwise noted, all NMR measurements were carried out at 25°C. The chemical shifts in the ^1H NMR spectra are recorded relative to $(\text{CH}_3)_4\text{Si}$ (δ 0.00 in CDCl_3) or the solvent peak (δ 1.94 in CD_3CN and δ 2.50 in $\text{DMSO}-d_6$), and the chemical shifts in the ^{13}C NMR are recorded relative to the solvent peak (δ 77.16 in CDCl_3 , δ 1.32 in CD_3CN , and δ 39.52 in $\text{DMSO}-d_6$). The abbreviations s, d, t, q, m, and br signify singlet, doublet, triplet, quartet, multiplet, and broad, respectively. HRMS spectra were measured by JEOL JMS-T100LC AccuTOF. Elemental analyses were performed at A Rabbit Science Japan Co., Ltd. Column chromatography was performed with Fuji Silysia, PSQ60B silica gel. Preparative TLC (PTLC) was carried out using Wakogel® B-5F silica gel. Visualization was accomplished with UV light (254 nm). The chiral HPLC analyses were carried out by using a chiral column equipped with a multiwavelength detector.

All reactions were performed with dry glassware under the atmosphere of nitrogen unless otherwise noted. Starting materials, imino esters **1**¹¹ and sulfocoumarins **4**¹² were prepared and identified by reported methods. Racemate products **3** and **5** were synthesized by using PPh₃ as the ligand. 1-propene-1,3-sultone (**2**) and other commercial compounds were used without further purification.

Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Glycine Imino Esters **1 with 1-Propene-1,3-sultone (**2**).** A mixture of [Cu(MeCN)₄]BF₄ (3.2 mg, 10 µmol, 5.0 mol%), (S)-DTBM-Segphos **L2** (13.0 mg, 11 µmol, 5.5 mol%) were dissolved in dry CH₂Cl₂ (1.0 mL) at room temperature, and 3Å MS (200 mg) was subsequently added to the mixture. After stirring at the same temperature for 30 min, *p*-chloro phenyl-substituted imino esters **1a** (43.2 mg, 0.20 mmol, 1.0 equiv.) and 1-propene-1,3-sultone (**2**) (26.4 mg, 0.22 mmol, 1.1 equiv.) were added successively. After stirring for 16 h at room temperature, the mixture was diluted with EtOAc (20-30 mL), filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude product showed that the *exo*-diastereomer is the sole product. The residue was purified by PTLC (*n*-hexane/EtOAc = 2/1) to give methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(4-chlorophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (**3a**) (66.2 mg, 0.20 mmol, 98% yield, 97% ee) as a colorless solid.

5 mmol Scale Experiment for the Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Esters **1a with Sultone **2**.** A mixture of [Cu(MeCN)₄]BF₄ (93.2 mg, 0.30 mmol, 5.9 mol%), (S)-DTBM-Segphos **L2** (324 mg, 0.324 mmol, 5.5 mol%) were dissolved in dry CH₂Cl₂ (20 mL), and 3Å MS (4.20 g) was subsequently added to the mixture. After stirring at room temperature for 30 min, *p*-chloro phenyl-substituted imino esters **1a** (1.06 g, 5.0 mmol, 1.0 equiv.) and sultone **2** (660 mg, 5.5 mmol, 1.1 equiv.) were added successively. After stirring for 16 h at room temperature, the mixture was diluted with EtOAc (80 mL), filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude product showed that the *exo*-diastereomer is the sole product. The residue was purified by silica gel column chromatography (*n*-

hexane/EtOAc = 2/1) to give methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(4-chlorophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (**3a**) (1.65 mg, 4.99 mmol, 99% yield, 98% ee) as a colorless solid.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(4-chlorophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3a). Yield: 98% (66.2 mg, 0.200 mmol, 98% ee); colorless solid; mp 80–82 °C; ¹H NMR (400 MHz, DMSO): δ 7.46 (s, 4H), 4.56 (dd, *J* = 1.8, 10.2 Hz, 1H), 4.46–4.40 (m, 2H), 3.96–3.89 (m, 2H), 3.89–3.64 (m, 1H), 3.70 (s, 3H); ¹³C NMR (100 MHz, CD₃CN): δ 171.2, 139.1, 132.7, 129.2, 128.7, 70.1, 64.7, 64.3, 63.6, 52.3, 47.5; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); *t*_R = 14.9 min (minor), 16.5 min (major); [α]_D²⁵ +11.2 (*c* 0.06, MeOH); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₃H₁₅ClNO₅S⁺, 332.0360; found 332.0348.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(4-bromophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3b). Yield: 99% (75.1 mg, 0.200 mmol, 96% ee); colorless solid; mp 104–106 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.43 (d, *J* = 8.4 Hz, 2H), 7.31 (d, *J* = 8.4 Hz, 2H), 4.56 (d, *J* = 6.7 Hz, 1H), 4.45–4.35 (m, 2H), 3.84 (d, *J* = 8.4 Hz, 1H), 3.74 (s, 3H), 3.60–3.42 (m, 2H), 2.56 (br s, 1H); ¹³C NMR (101 MHz, CDCl₃): δ 170.6, 137.8, 132.0, 128.5, 122.5, 69.0, 65.1, 64.1, 63.7, 52.8, 47.8; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); *t*_R = 11.0 min (minor), 12.0 min (major); [α]_D²⁵ +4.68 (*c* 0.05, MeOH); HRMS (ESI) *m/z*: [M+Na]⁺ calcd for C₁₃H₁₄BrNNaO₅S⁺, 397.9674; found 397.9657.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(4-fluorophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3c). Yield: 91% (57.1 mg, 0.181 mmol, 98% ee); colorless solid; mp 133–135 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.51–7.47 (m, 2H), 7.15–7.11 (m, 2H), 4.56 (d, *J* = 7.2 Hz, 1H), 4.50 (dd, *J* = 1.7, 10.2 Hz, 1H), 4.44 (dd, *J* = 5.8, 10.2 Hz, 1H), 3.90 (d, *J* = 8.2 Hz, 1H), 3.76 (dd, *J* = 7.2, 9.8 Hz, 1H), 3.73 (s, 3H), 3.69–3.65 (m, 1H), 3.08 (br s, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 171.9, 163.4 (d, *J*_{C-F} = 244 Hz), 136.7 (d, *J*_{C-F} = 3.0 Hz), 130.1 (d, *J*_{C-F} = 8.4 Hz), 116.3 (d, *J* = 21.7 Hz), 70.7, 65.9, 65.3, 64.7, 52.9, 48.8; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0

mL/min, 220 nm); t_R = 23.5 min (minor), 24.7 min (major); $[\alpha]_D^{25} +18.7$ (c 0.05, MeOH); HRMS (ESI) m/z : [M+H]⁺ calcd for C₁₃H₁₅FNO₅S⁺, 316.0650; found 316.0658.

Methyl (3aS, 4S, 6S, 6aR)-6-(4-(trifluoromethyl)phenyl)hexahydro-[1,2]oxathiolo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3d). Yield: 95% (69.2 mg, 0.189 mmol, 95% ee); colorless solid; mp 113–115 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.70 (d, J = 8.4 Hz, 2H), 7.65 (d, J = 8.4 Hz, 2H), 4.67 (d, J = 6.9 Hz, 1H), 4.52 (dd, J = 1.8, 10.2 Hz, 1H), 4.46 (dd, J = 5.8, 10.2 Hz, 1H), 3.93 (d, J = 8.2 Hz, 1H), 3.80 (dd, J = 6.9, 9.8 Hz, 1H), 3.73 (s, 3H), 3.69–3.62 (m, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 172.0, 145.6, 130.4 (q, J_{C-F} = 32.2 Hz), 128.7, 126.5 (q, J_{C-F} = 3.9 Hz), 125.4 (q, J_{C-F} = 271.1), 70.9, 65.9, 65.3, 64.7, 52.9, 48.7; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 7.7 min (minor), 8.5 min (major); $[\alpha]_D^{25} -17.8$ (c 0.05, MeOH); HRMS (ESI) m/z : [M+H]⁺ calcd for C₁₄H₁₅F₃NO₅S⁺, 366.0623; found 366.0629.

Methyl (3aS, 4S, 6S, 6aR)-6-(4-methoxyphenyl)hexahydro-[1,2]oxathiolo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3e). Yield: 99%, (65.0 mg, 0.199 mmol, 96% ee); colorless solid; mp 186 °C (decomp.); ¹H NMR (400 MHz, CDCl₃): δ 7.37 (d, J = 8.6 Hz, 2H), 6.86 (d, J = 8.6 Hz, 2H), 4.57 (d, J = 7.0 Hz, 1H), 4.46–4.43 (m, 2H), 3.85 (d, J = 8.6 Hz, 1H), 3.78 (s, 3H), 3.77 (s, 3H), 3.61 (dd, J = 7.0, 10.0 Hz, 1H), 3.54–3.46 (m, 1H), 2.49 (br s, 1H); ¹³C NMR (101 MHz, CDCl₃): δ 170.8, 159.6, 130.6, 128.0, 114.2, 68.9, 65.3, 64.3, 64.2, 55.3, 52.7, 48.3; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 17.9 min (minor), 19.4 min (major); $[\alpha]_D^{25} +7.44$ (c 0.05, CHCl₃); HRMS (ESI) m/z : [M+Na]⁺ calcd for C₁₄H₁₇NO₆S⁺, 350.0674; found 350.0686.

Methyl (3aS, 4S, 6S, 6aR)-6-(4-tolyl)hexahydro-[1,2]oxathiolo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3f). Yield: 99% (62.3 mg, 0.200 mmol, 93% ee, 1.1 equiv. of **1f** to **2** was used); colorless solid; mp 93–95 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.35 (d, J = 7.8 Hz, 2H), 7.17 (d, J = 7.8 Hz, 2H), 4.60 (d, J = 6.3 Hz, 1H), 4.49–4.40 (m, 2H), 3.86 (d, J = 8.2 Hz, 1H), 3.77 (s, 3H), 3.68–3.60 (m, 1H), 3.55–3.45 (m, 1H), 2.32 (s, 3H); ¹³C NMR (101 MHz, CDCl₃): δ 170.8, 138.3, 135.6, 129.5, 126.6, 68.9, 65.4, 64.4, 64.3, 52.7,

48.4, 21.0; HPLC (Daicel Chiralpak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 11.1 min (minor), 12.5 min (major); $[\alpha]_D^{25} +9.30$ (*c* 0.05, CHCl₃); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₄H₁₈NO₅S⁺, 312.0908; found 312.0906.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-phenylhexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3g). Yield: 90% (53.8 mg, 0.181 mmol, 99% ee); colorless solid; mp 138–140 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.48–7.32 (m, 5H), 4.56 (d, *J* = 7.2 Hz, 1H), 4.51 (dd, *J* = 1.7, 10.2 Hz, 1H), 4.44 (dd, *J* = 5.7, 10.2 Hz, 1H), 3.88 (d, *J* = 8.4 Hz, 1H), 3.78 (dd, *J* = 7.2, 9.9 Hz, 1H) 3.73 (s, 3H), 3.67–3.60 (m, 1H), 2.69 (br s, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 172.0, 140.7, 129.7, 129.2, 128.0, 70.7, 66.1, 65.5, 65.4, 52.9, 49.1; HPLC (Daicel Chiralpak IH-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 30.0 min (minor), 36.3 min (major); $[\alpha]_D^{25} +13.9$ (*c* 0.04, MeOH); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₃H₁₆NO₅S⁺, 298.0744; found 298.0731.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(3-fluorophenyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3h). Yield: 97%, (63.5 mg, 0.201 mmol, 98% ee); colorless solid; mp 128–130 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.43–7.38 (m, 1H), 7.30–7.23 (m, 2H), 7.10–7.06 (m, 1H), 4.61 (d, *J* = 7.0 Hz, 1H), 4.51 (dd, *J* = 1.8, 10.2 Hz, 1H), 4.44 (dd, *J* = 5.7, 10.2 Hz, 1H), 3.91 (d, *J* = 8.3 Hz, 1H), 3.78 (dd, *J* = 7.0, 9.7 Hz, 1H), 3.73 (s, 3H), 3.68–3.62 (m, 1H), 3.06 (br s, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 171.9, 163.8 (d, *J*_{C-F} = 244 Hz), 143.7 (d, *J*_{C-F} = 7.3 Hz), 131.6 (d, *J*_{C-F} = 8.4 Hz), 124.0 (d, *J*_{C-F} = 2.8 Hz), 115.8 (d, *J*_{C-F} = 21.4 Hz), 114.7 (d, *J*_{C-F} = 22.8 Hz), 70.8, 65.9, 65.2, 64.7 (d, *J* = 1.9 Hz), 53.0, 48.7; HPLC (Daicel Chiralpak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 14.4 min (major), 18.5 min (minor); $[\alpha]_D^{25} +10.8$ (*c* 0.05, MeOH); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₃H₁₅FNO₅S⁺, 316.0664; found 316.0655.

Methyl (3a*S*, 4*S*, 6*S*, 6a*R*)-6-(3-tolyl)hexahydro-[1,2]oxathiolo[3,4-*c*]pyrrole-4-carboxylate 1,1-dioxide (3i). Yield: 96% (59.8 mg, 0.192 mmol, 93% ee, 1.1 equiv. of **1i** to **2** was used); colorless solid; mp 75–78 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.27–7.22 (m, 3H), 7.15 (d, *J* = 6.9 Hz, 1H), 4.51–4.46 (m, 2H), 4.43 (dd, *J* = 5.7, 10.2 Hz, 1H), 3.86 (d, *J* = 8.3 Hz, 1H), 3.76 (dd, *J* = 7.1, 9.9 Hz, 1H), 3.73 (s, 3H), 3.64–3.58 (m, 1H), 2.78

Methyl (3aS, 4S, 6S, 6aR)-6-(2-bromophenyl)hexahydro-[1,2]oxathiololo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3j). Yield: 89% (66.8 mg, 0.178 mmol, 94% ee, 1.1 equiv. of **1j** to **2** was used); colorless solid; mp 138–140 °C; ^1H NMR (400 MHz, CD₃CN): δ 7.79 (dd, *J* = 1.7, 7.8 Hz, 1H), 7.61 (dd, *J* = 1.1, 7.9 Hz, 1H), 7.41 (dt, *J* = 1.0, 7.4 Hz, 1H), 7.23 (dt, *J* = 1.7, 7.6 Hz, 1H), 5.13 (d, *J* = 3.8 Hz, 1H), 4.55 (d, *J* = 9.9 Hz, 1H), 4.44 (dd, *J* = 5.1, 10.1 Hz, 1H), 4.06 (d, *J* = 8.7 Hz, 1H), 3.86 (dd, *J* = 3.8, 8.7 Hz, 1H), 3.73 (s, 3H), 3.63-3.57 (m, 1H); ^{13}C NMR (101 MHz, CD₃CN): δ 172.9, 141.2, 133.8, 130.7, 130.3, 128.9, 123.6, 70.5, 67.0, 65.0, 63.8, 52.9, 48.5; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_{R} = 15.3 min (major), 17.2 min (minor); $[\alpha]_{\text{D}}^{25} +36.6$ (*c* 0.05, MeOH); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₃H₁₅BrNO₅S⁺, 375.9854; found 375.9839.

Methyl (3aS, 4S, 6S, 6aR)-6-(2-tolyl)hexahydro-[1,2]oxathiololo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3k). Yield: 93% (57.8 mg, 0.186 mmol, 98% ee, 1.1 equiv. of **1k** to **2** was used); colorless solid; mp 113–115 °C; ^1H NMR (400 MHz, CD₃CN): δ 7.51-7.49 (m, 1H), 7.26-7.18 (m, 3H), 4.84 (d, *J* = 6.3 Hz, 1H), 4.55-4.42 (m, 2H), 3.94 (d, *J* = 8.6 Hz, 1H), 3.86 (dd, *J* = 6.9, 9.5 Hz, 1H), 3.72 (s, 3H), 3.70-3.65 (m, 1H) 2.43 (s, 3H); ^{13}C NMR (101 MHz, CD₃CN): δ 172.1, 138.6, 137.4, 131.5, 129.0, 128.1, 127.4, 70.7, 66.2, 65.4, 61.6, 52.9, 49.3, 19.5; HPLC (Daicel Chiraldak IH-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_{R} = 21.0 min (minor), 34.7 min (major); $[\alpha]_{\text{D}}^{25} +27.8$ (*c* 0.06, CHCl₃); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₄H₁₈NO₅S⁺, 312.0906; found 312.0918.

Methyl (3aS, 4S, 6R, 6aR)-6-(2-thienyl)hexahydro-[1,2]oxathiololo[3,4-c]pyrrole-4-carboxylate 1,1-dioxide (3l). Yield: 94% (56.9 mg, 0.188 mmol, 95% ee); colorless solid;

mp 147–149 °C; ^1H NMR (400 MHz, CD₃CN): δ 7.36 (dd, J = 1.2, 5.1 Hz, 1H), 7.11–7.10 (m, 1H), 7.01 (dd, J = 3.5, 5.1 Hz, 1H), 4.83 (t, J = 6.7 Hz, 1H), 4.48 (dd, J = 1.9, 10.2 Hz, 1H), 4.43 (dd, J = 5.7, 10.2 Hz, 1H), 3.88 (dd, J = 6.9, 7.8 Hz, 1H), 3.81 (dd, J = 6.9, 9.8 Hz, 1H), 3.71 (s, 3H), 3.70–3.64 (m, 1H), 3.11 (br s, 1H); ^{13}C NMR (100 MHz, CD₃CN): δ 171.8, 144.5, 128.1, 126.6, 126.0, 70.8, 66.2, 65.3, 61.4, 53.0, 48.5; HPLC (Daicel Chiraldak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_{R} = 15.4 min (major), 17.9 min (major); $[\alpha]_{\text{D}}^{25}$ −16.9 (*c* 0.03, MeOH); HRMS (DART) *m/z*: [M+H]⁺ calcd for C₁₁H₁₄NO₅S⁺, 304.0313; found 304.0308; CCDC 1993601.

Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Glycine Imino Esters 1 with Sulfocoumarins 4. A mixture of [Cu(MeCN)₄]BF₄ (3.2 mg, 10 μmol , 5.0 mol %), (*S*, *S_p*)-*t*Bu-FcPHOX **L5** (5.5 mg, 11 μmol , 5.5 mol %) were dissolved in dry Et₂O (1.0 mL), and 3 Å MS (200 mg) was subsequently added to the mixture. After stirring at room temperature for 30 min, *p*-chloro phenyl substituted imino esters **1a** (46.4 mg, 0.22 mmol, 1.1 equiv.) and sulfocoumarins **4a** (36.4 mg, 0.20 mmol, 1.0 equiv.) were added successively. After stirring for 16 h at room temperature, the mixture was diluted with EtOAc (20–30 mL), filtered through a short Celite pad, and concentrated under reduced pressure. ^1H NMR analysis of the crude product showed that the *exo*-diastereomer is the sole product. The residue was purified by PTLC (*n*-hexane/EtOAc = 2/1) to give methyl (1*S*, 3*S*, 3*aR*, 9*bR*)-3-(4-chlorophenyl)-2,3,3*a*,9*b*-tetrahydro-1*H*-benzo[5,6][1,2]oxathiino[3,4-*c*]pyrrole-1-carboxylate 4,4-dioxide (**5aa**) (71.0 mg, 0.180 mmol, 90% yield, 92% ee) as a colorless solid.

Methyl (1*S*, 3*S*, 3*aR*, 9*bR*)-3-(4-chlorophenyl)-2,3,3*a*,9*b*-tetrahydro-1*H*-benzo[5,6][1,2]oxathiino[3,4-*c*]pyrrole-1-carboxylate 4,4-dioxide (5aa). Yield: 90% (71.0 mg, 0.180 mmol, 92% ee); colorless solid; mp 110–112 °C; ^1H NMR (400 MHz, CD₃CN): δ 7.56–7.52 (m, 2H), 7.43–7.37 (m, 4H), 7.33–7.28 (m, 1H), 7.18 (dd, J = 1.6, 8.2 Hz, 1H), 4.87 (d, J = 6.6 Hz, 1H), 4.31 (dd, J = 7.7, 9.6 Hz, 1H), 4.20 (dd, J = 6.6, 9.6 Hz, 1H), 3.99 (d, J = 7.7 Hz, 1H), 3.78 (s, 3H), 3.14 (br s, 1H); ^{13}C NMR (101 MHz, CD₃CN): δ 173.1, 151.3, 140.5, 134.2, 130.8, 130.5, 130.1, 129.5, 127.6, 124.7, 120.4,

67.8, 65.9, 63.7, 53.2, 47.2; HPLC (Daicel Chiralpak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 11.3 min (minor), 18.4 min (major); $[\alpha]_D^{25} +2.80$ (c 0.06, MeOH); Anal. calcd for C₁₈H₁₆ClNO₅S: C, 54.90; H, 4.10; N, 3.56. found C, 54.91; H, 4.17; N, 3.62%.

Methyl (1*S*, 3*S*, 3*aR*, 9*bR*)-3-(4-bromophenyl)-2,3,3*a*,9*b*-tetrahydro-1*H*-benzo[5,6][1,2]oxathiino[3,4-*c*]pyrrole-1-carboxylate 4,4-dioxide (5ba). Yield: 99% (87.0 mg, 0.199 mmol, 94% ee); colorless solid; mp 92–94 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.58–7.52 (m, 2H), 7.50–7.46 (m, 2H), 7.42–7.37 (m, 2H), 7.30 (ddd, *J* = 1.3, 7.6, 7.6 Hz, 1H), 7.19–7.15 (m, 1H), 4.86 (d, *J* = 6.4 Hz, 1H), 4.31 (dd, *J* = 7.6, 9.6 Hz, 1H), 4.20 (dd, *J* = 6.4, 9.6 Hz, 1H), 3.99 (d, *J* = 7.6 Hz, 1H), 3.78 (s, 3H), 3.14 (br s, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 173.1, 151.3, 141.0, 132.5, 130.8, 130.5, 130.4, 127.6, 124.6, 122.4, 120.4, 67.8, 65.8, 63.7, 53.2, 47.2; HPLC (Daicel Chiralpak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 11.6 min (minor), 19.9 min (major); $[\alpha]_D^{25} +2.18$ (c 0.05, MeOH); Anal. calcd for C₁₈H₁₆BrNO₅S: C, 49.33; H, 3.68; N, 3.20. found C, 49.17; H, 3.67; N, 3.15%.

Methyl (1*S*, 3*S*, 3*aR*, 9*bR*)-3-phenyl-2,3,3*a*,9*b*-tetrahydro-1*H*-benzo[5,6][1,2]oxathiino[3,4-*c*]pyrrole-1-carboxylate 4,4-dioxide (5ga). Yield: 86% (61.6 mg, 0.171 mmol, 90% ee); colorless solid; mp 99–101 °C; ¹H NMR (400 MHz, CD₃CN): δ 7.54 (d, *J* = 7.3 Hz, 2H), 7.46–7.28 (m, 6H), 7.18 (d, *J* = 8.0 Hz, 1H), 4.86 (d, *J* = 6.6 Hz, 1H), 4.32 (dd, *J* = 7.8, 9.7 Hz, 1H), 4.23 (dd, *J* = 6.6, 9.7 Hz, 1H), 3.98 (d, *J* = 7.8 Hz, 1H), 3.79 (s, 3H), 2.94 (br s, 1H); ¹³C NMR (101 MHz, CD₃CN): δ 173.1, 151.4, 141.4, 130.8, 130.4, 129.6, 129.2, 128.4, 127.6, 124.9, 120.4, 67.9, 66.0, 64.6, 53.2, 47.5; HPLC (Daicel Chiralpak ID-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 14.0 min (minor), 20.6 min (major); $[\alpha]_D^{25} +8.31$ (c 0.04, MeOH); HRMS (ESI) *m/z*: [M+H]⁺ calcd for C₁₈H₁₈NO₅S⁺, 360.0900; found 360.0892.

X-ray Crystallographic Analysis. The crystallographic data of *exo*-**3I** and *exo*-**5la** were summarized in Table S2-1. Single crystals of *exo*-**3I** and *exo*-**5la** were prepared from CH₂Cl₂/MeCN co-solvent by vapor diffusion technique using *n*-hexane as the anti-solvent. A suitable single crystal was selected and mounted on the glass fiber and transferred to the goniometer of a Rigaku VariMax Saturn CCD diffractometer with graphite-monochromated Mo K α radiation ($\lambda = 71.073$ pm). Yadokari-XG 2009 program was used as a graphical interface. The structure was solved and refined by SIR-2004 by SHELX-97 programs. The refinement was performed anisotropically for all non-hydrogen atoms. Hydrogen atoms were placed using AFIX instructions. The crystallographic data of *exo*-**3I** and *exo*-**5la** were summarized in Table S2-1.

Table S2-1. Crystal data and structure refinements for *exo*-**3l** and *exo*-**5la**.

Chapter 3

Silver-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Esters with Ylidene-2,3-dioxopyrrolidines

3–1. Introduction

Spirocyclic pyrrolidines are among the most important units that are present in numerous naturally occurring alkaloids, drugs, and pharmaceutically active compounds (Figure 3-1).¹ Therefore, the structurally and stereochemically diverse preparation of these molecules would have the potential to aid in drug discovery.

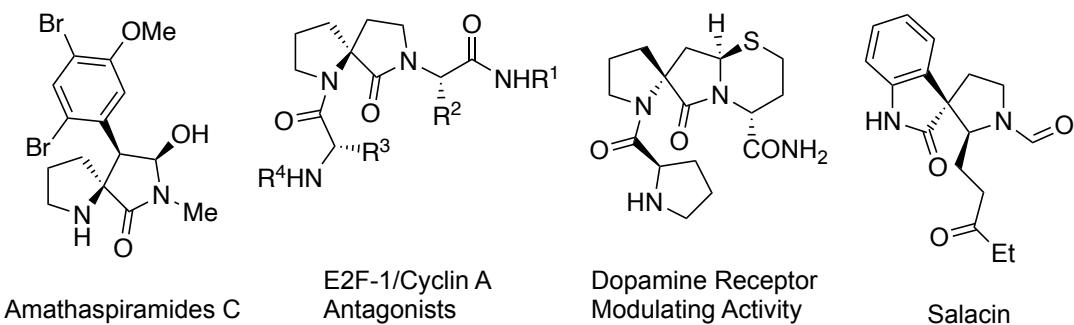

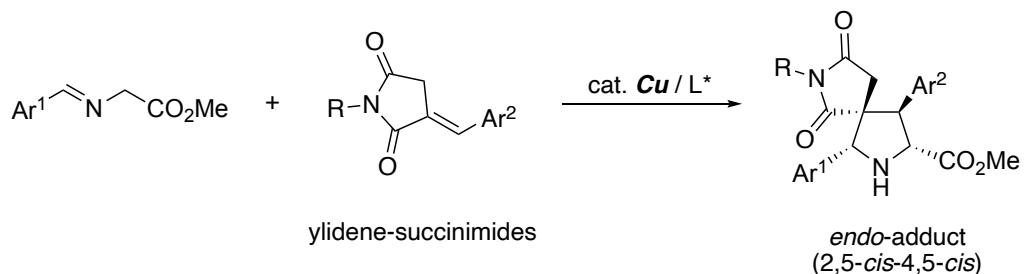

Figure 3-1. Examples of biologically active compounds containing spiropyrrolidines.

This has prompted many research groups to develop efficient synthetic methodologies to construct the scaffold by using intramolecular cyclization² and intermolecular 1,3-DC.³ Among them, the catalytic asymmetric 1,3-DC of azomethine ylides with a variety of electron-deficient alkene dipolarophiles has been a robust synthetic tool for the construction of structurally diverse pyrrolidine derivatives with access to spirocyclic pyrrolidines with chiral quaternary centers.⁴ However, this method is not suitable for the stereodivergent preparation of spiropyrrolidines; 2,5-*cis* configurations such as *endo*- and *exo*-adducts are usually formed, and 2,5-*trans* configurations such as *endo'*- and *exo'*-adducts are difficult to obtain.⁵ Indeed, a variety of exocyclic alkenes such as 2-oxoindolin-3-ylidenes,⁶ 2-alkylidene-cycloketones,⁷ and α -methylene- γ -butyrolactones⁸ have been proposed as dipolarophiles to construct chiral spirocyclic pyrrolidine skeletons for azomethine ylides, but most of them afforded 2,5-*cis* cycloadducts. For example, Deng and co-workers revealed that the chiral copper-catalyzed (3+2) cycloaddition of azomethine ylides with α -alkylidene succinimides⁹ and its sulfur analog thiazolidinediones provided spirocyclic pyrrolidines as *endo*-

diastereomers (Figure 3-2a). On the other hand, the *exo'*-selective construction of spiropyrrolidines is limited to a single example developed by Arai and co-workers, which is a nickel complex-catalyzed reaction of imino esters with 2-oxoindolin-3-ylidenes.^{6c}

In this study, the author focused on 4-ylidene-2,3-dioxopyrrolidines, which are good Michael acceptors in the organocatalyzed asymmetric hetero-DA reactions and Michael addition/cyclization reactions.¹⁰ However, examples for the spirocyclic construction are limited; the synthesis of spirooxyindoles by the (3+2) cycloaddition reaction of 4-ylidene-2,3-dioxopyrrolidines with *N*-2,2,2-trifluoroethylisatin ketimines is the only example.¹¹ Thus, the author envisioned that asymmetric (3+2) cycloaddition of imino esters with 4-ylidene-2,3-dioxopyrrolidines would provide a new method for the construction of spiropyrrolidines (Figure 3-2b). The reaction was catalyzed by a chiral silver complex and proceeded with an unusual *exo'*-diastereoselectivity. In addition, a chiral ligand TCF developed by our groups¹² was the most efficient for enantioselective preparation of the cycloadducts.

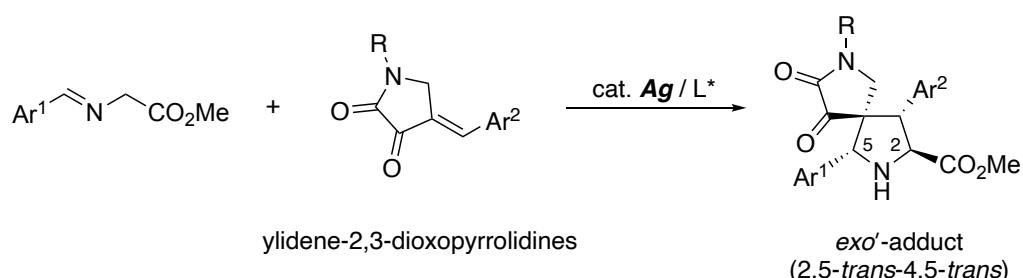

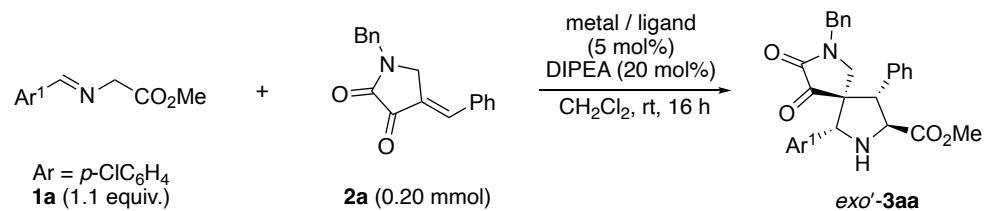

Figure 3-2. (a) Previous report on construction of spiropyrrolidines and (b) this work.

3–2. Results and Discussion

The author first carried out the reaction of *p*-chloro phenyl-substituted imino ester **1a** with ylidene-2,3-dioxopyrrolidine **2a** in CH₂Cl₂ at room temperature for 16 h in the presence of silver acetate (AgOAc, 5.0 mol%), (*R*, *S_p*)-TCF **L1** (5.0 mol%), and diisopropylethylamine (DIPEA, 20 mol%). The (3+2) cycloaddition smoothly yielded the corresponding spiropyrrolidines with high diastereo- and enantioselectivity (Table 3-1, entry 1). The major product could be isolated by column chromatography and was determined to be the *exo'*-diastereomer, which is rarely obtained in the (3+2) cycloaddition of imino esters (details of stereochemistry are shown in Figure 3-6 below). On the other hand, there were two other diastereomers in addition to the major cycloadduct. However, they were difficult to isolate and purify by column chromatography, and their structures could not be determined.

The author next conducted screening of silver and copper complexes that are frequently applied to the cycloaddition reaction.^{4,5} The ligands employed in this study are shown in Figure 3-3. Several ferrocene-based ligands such as Fesulphos **L2** and FcPHOX **L3**, were not effective under the silver-catalyzed condition and decreased the diastereo- and enantioselectivity (Table 3-1, entries 2, 3). The reaction using BINAP **L4** and Segphos **L5** as the ligands also resulted in high yield, but with lower stereoselectivity than when TCF **L1** was used. When [Cu(MeCN)₄]BF₄ was applied to the reaction as the metal salt, the diastereoselectivity increased (entries 6-10). However, none of the ligands were effective for the reaction, giving the *exo'*-adducts with low to moderate enantioselectivity. Therefore, it was revealed that our original AgOAc/TCF complex was superior in the *exo'*-diastereo- and enantioselective cycloaddition of imino ester **1a** with ylidene-2,3-dioxopyrrolidine **2a**. Subsequently, the author carried out further examinations using the AgOAc/TCF complex.

[a] Condition: **1a** (0.22 mmol), **2a** (0.20 mmol), metal salt (5.0 mol%), ligand (5.5 mol%), DIPEA (20 mol%), CH₂Cl₂ (1 mL), rt, 16 h. [b] Isolated yield. [c] Determined by crude ¹H NMR. [d] Determined by chiral HPLC. [e] Combined yield.

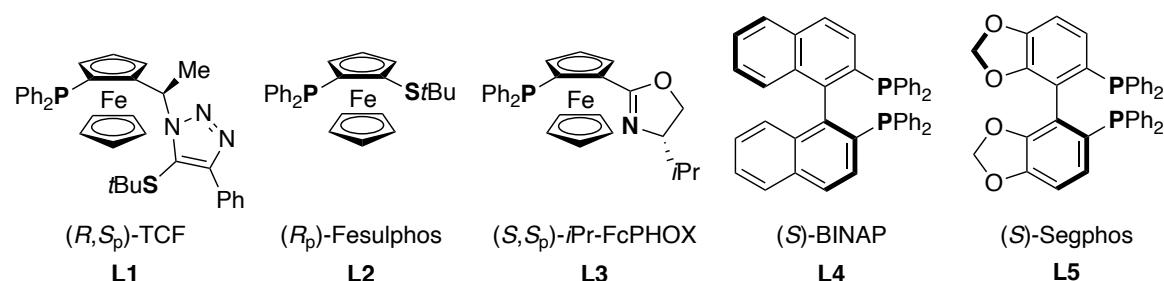

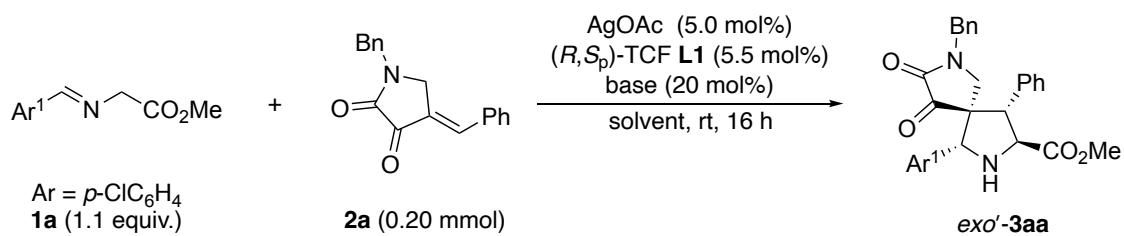

Figure 3-3. Chiral ligands employed in this study.

The reaction conditions were optimized and the results are shown in Table 3-2. It was revealed that the silver/TCF complex-catalyzed reaction of imino ester **1a** with ylidene-2,3-dioxopyrrolidines **2a** proceeded with excellent yield, diastereo- and

enantioselectivity in the presence of AgOCOCF_3 as the metal salt and Et_3N as the base in THF at 0 °C (entry 1). The enantioselectivity when the reaction was carried out at 0 °C was 96% ee, whereas at room temperature it decreased to 90% ee (entry 2). AgOCOCF_3 was the most suitable for giving the desired product with a high yield, with other silver salts such as AgOTf , AgF , and AgOAc giving the cycloadducts in moderate to good yield

Table 3-2. Optimization of the reaction conditions^a

(entry 2-5). Although the addition of base was not always required for the reaction, the product **3aa** was obtained in high yield and excellent enantioselectivity when Et₃N was used as the additive (entries 5-7). The yield and stereoselectivity of the product were decreased when DBU was added to the reaction (entry 8). THF was selected as the most suitable solvent because other solvents such as Et₂O, MTBE, toluene, and CH₂Cl₂ resulted in low yield (entries 9-13).

The scope of imino esters **1** under the optimal reaction conditions was investigated next, and the results are summarized in Figure 3-4. It was revealed that a wide range of imino esters **1** was applicable for the stereoselective (3+2) cycloaddition. When *para*-fluoro- and bromo-substituted imino esters **1b** and **1c** were applied to the reaction, the corresponding spiropyrrolidines **3ba** and **3ca** were obtained with excellent yield and enantioselectivity. *meta*-Chloro-substituted imino ester **1d** also gave the cycloadduct **3da** as a single diastereomer, but the yield was moderate. Imino esters **1e** and **1f** bearing methyl groups at the *para*- and *meta*-positions successfully gave the corresponding products **3ea** and **3fa** with excellent yield and stereoselectivity, and an *ortho*-substituent could also be applied to the reaction with slightly lower values. Although the strong electron-withdrawing CF₃ group gave a moderate yield and diastereoselectivity, the high enantioselectivity was maintained. The strong electron-donating methoxy group was successfully applied to the reaction, giving the product **3ia** with excellent stereoselectivity. The phenyl group with no substituent smoothly reacted with 2,3-dioxopyrrolidine **2a**, and a thiienyl group could also be used in the stereoselective (3+2) cycloaddition.

Additionally, the optimal reaction conditions could be applied to a wide range of ylidene-2,3-dioxopyrrolidines **2** for the asymmetric reaction (Figure 3-5). For example, when 2,3-dioxopyrrolidines with *para*-substituted aryl groups were used, the corresponding spiropyrrolidines **3ab**, **3ac**, **3ad**, and **3ae** were obtained with excellent enantioselectivity. Substituents at the *meta*-position maintained excellent enantioselectivity, but the diastereoselectivity was slightly decreased. An *ortho*-methyl

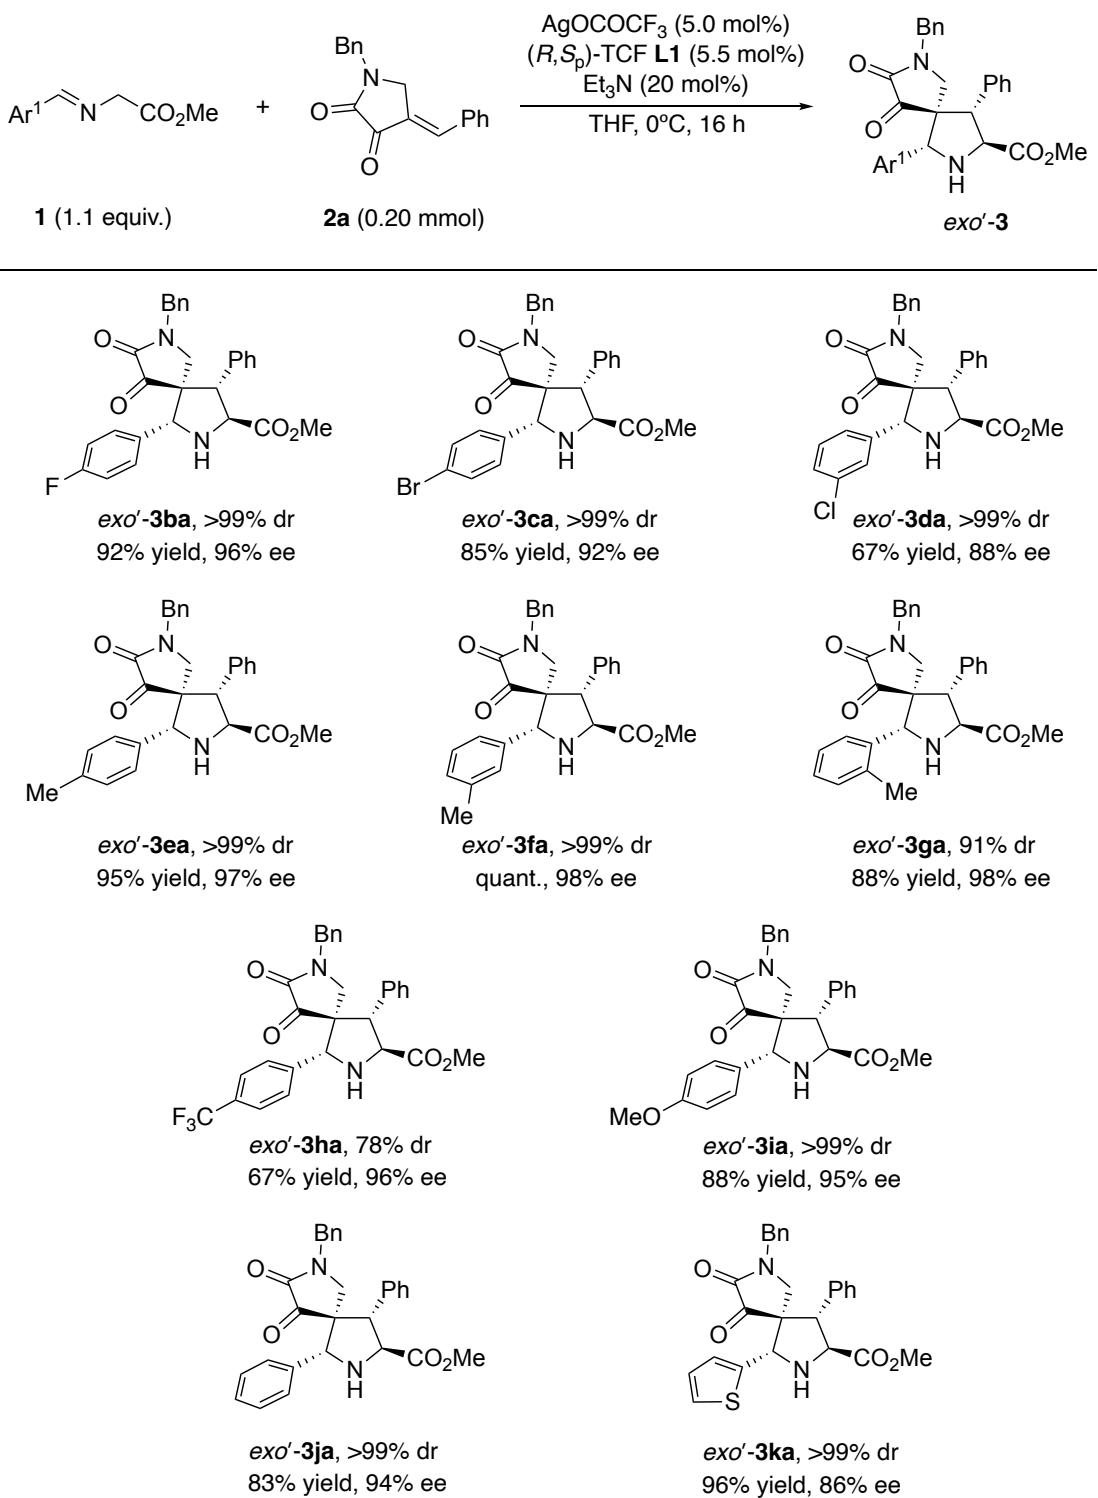

Figure 3-4. Scope of imino esters **1**.

group slightly decreased the stereoselectivity to give the cycloadducts **3ah**. 2,3-Dioxopyrrolidines bearing a 2-thienyl group efficiently reacted with imino esters **1a**, giving the products **3ai** with excellent enantioselectivity. These results indicated that the substituent of the 2,3-dioxopyrrolidines **2** had some influence on the reaction, but they could be applied with high enantioselectivity.

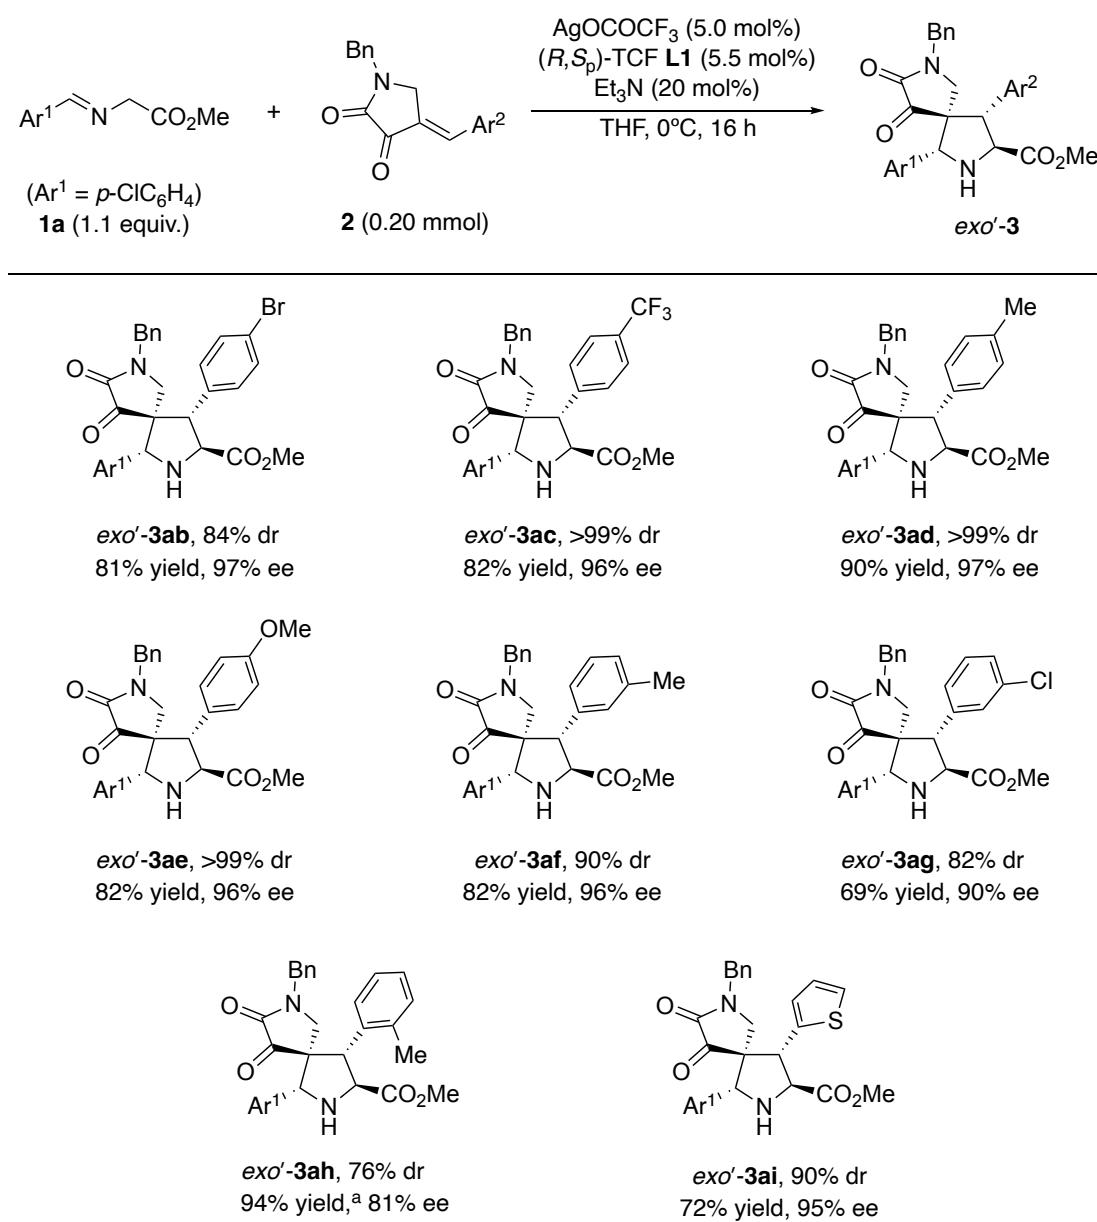

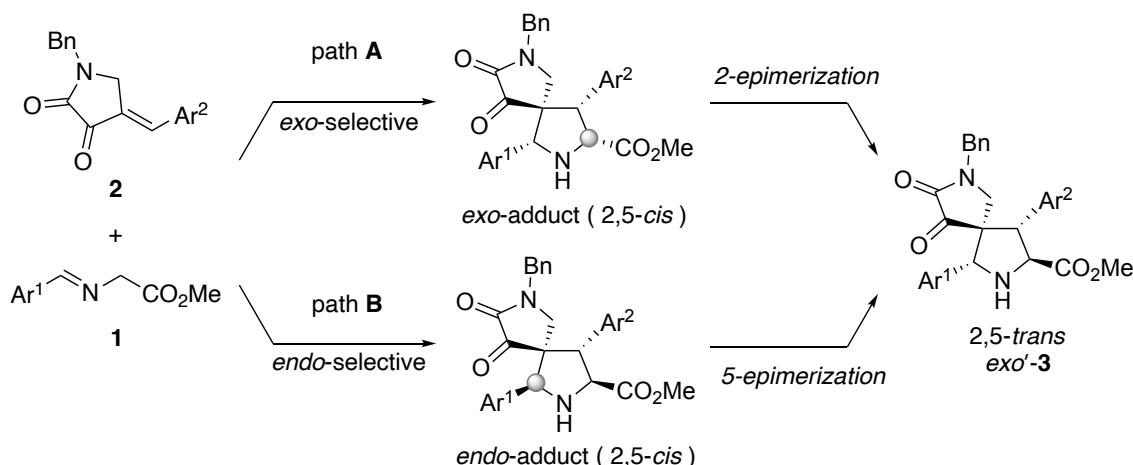

Figure 3-5. Scope of ylidene-2,3-dioxopyrrolidines **2**. [a] Combined yields are shown.

The metal complex-catalyzed (3+2) cycloaddition of imino esters **1** with activated olefins generally proceeds with *exo*- or *endo*-diastereoselectivity (2,5-*cis* configuration).^{4,5} On the other hand, the formation of 2,5-*trans* diastereomers such as *exo'*-adducts is unusual and has been limited to a few examples.^{6c,13} The author was interested in the unexpected stereochemical outcome and engaged in experiments to elucidate details of this diastereoselectivity. With the previous reports in mind, *exo'*-cycloadducts might be formed via base-promoted epimerization of the first generated 2,5-*cis* pyrrolidines (Scheme 3-1).^{13e,14} According to this viewpoint, two reaction pathways are possible. One is the epimerization of the 2-position of the pyrrolidine ring after the formation of *exo*-cycloadducts by the 1,3-DC of imino esters **1** with 2,3-dioxopyrrolidines **2** (path A). Another is the *endo*-selective formation and subsequent 5-epimerization of the pyrrolidine ring (path B).

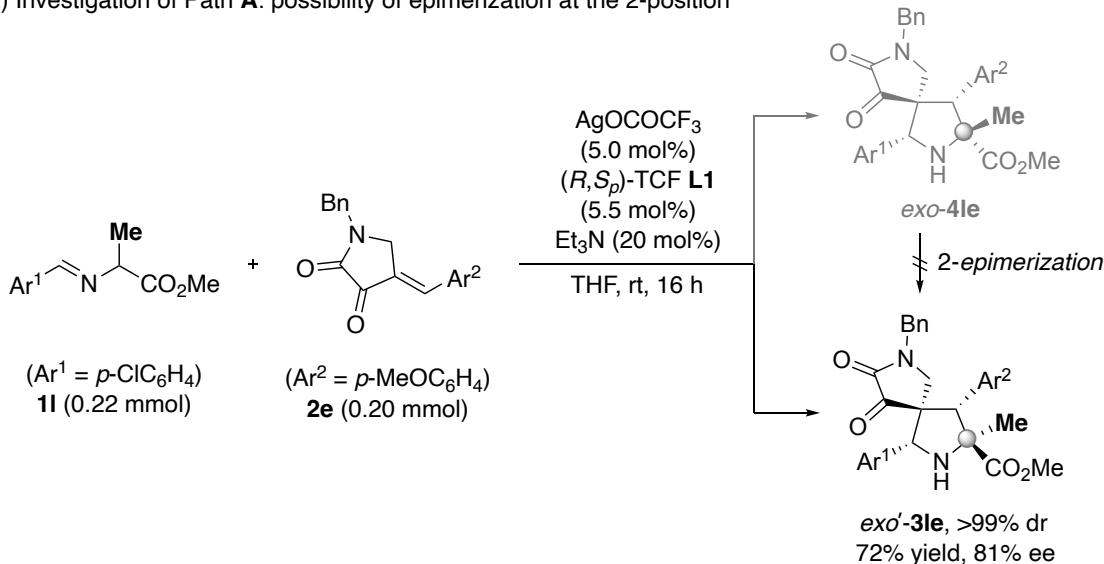

Scheme 3-1. Possible epimerization pathways to afford *exo'*-cycloadducts.

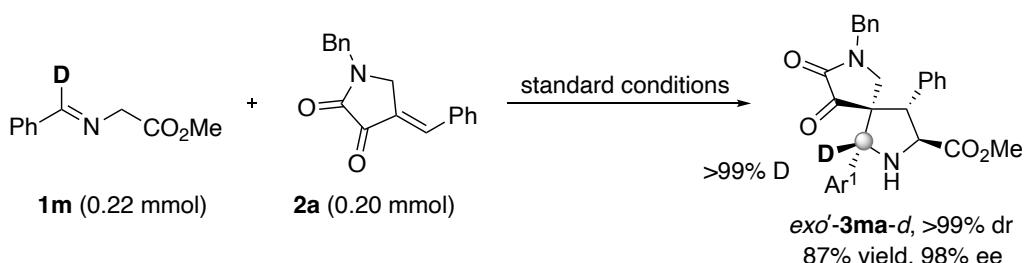

To investigate the possibility of the 2,5-*trans* pyrrolidines being generated by the 2-epimerization after the first formed *exo*-cycloadducts, an initial control experiment was conducted with the α -methyl-substituted imino esters **1I** derived from (\pm) -alanine as the azomethine ylide precursor (Scheme 3-2a). In this case, if the *exo*-**4le** (2,5-*cis* configuration) was generated as the intermediate via reaction pathway A, no epimerization at the 2-position would take place because this stereocenter is a quaternary carbon. As a result of the experiment, α -methyl-substituted imino ester **1I** reacted with

2,3-dioxopyrrolidines **2e** at room temperature, yielding *exo'*-cycloadducts as a single diastereomer. The racemic products *rac*-**3le** synthesized by using PPh₃ as the ligand were suitable for the preparation of a single crystal containing solvent THF, and the stereochemistry (2,5-*trans* configuration) could be determined by X-ray crystallographic analysis (Figure 3-6, right). This result indicated that *exo'*-adducts were not generated via *exo*-cycloadducts, ruling out the epimerization pathway A in Scheme 3-1.

(a) Investigation of Path A: possibility of epimerization at the 2-position

(b) Investigation of Path B: possibility of epimerization at the 5-position

Scheme 3-2. Control experiment for epimerization pathways.

A deuterium-labeled experiment was performed to investigate the possibility of the proposed *endo*-selective (3+2) cycloaddition and subsequent epimerization at the 5-position of the cycloadducts (Scheme 3-2b). Deuterium-labeled imino ester **1m-d** reacted with 2,3-dioxopyrrolidine **2a** under the optimized conditions, giving the corresponding *exo'*-**3ma-d** as a single diastereomer with high yield and excellent enantioselectivity. This control experiment gave 2,5-*trans* spiropyrrolidine *exo'*-**3ma-d** with >99% deuterium

ratio as a single stereoisomer. Thus, it was unlikely that 5-epimerization took place under the reaction conditions, and reaction pathway B in Scheme 3-1 was not reasonable for the mechanism for 2,5-*trans* stereochemistry.

A single crystal of chiral spiropyrrolidine *exo*'-3ae was suitable for the X-ray crystallographic analysis (Figure 3-6, left). The absolute configuration of several chiral centers could be determined; the 2, 3, 4, and 5-positions of the pyrrolidine ring were *S*, *S*, *R*, and *R*, respectively. In general, the stereochemistry of the 2-position depends on the chirality of the ligand used, and this is consistent with previous reports using (*R*, *S_p*)-TCF.¹² Therefore, the point of interest is the stereochemistry of the 5-position, in which the aryl group is placed *trans* to the methoxy carbonyl group at the 2-position (2,5-*trans* configuration). As described above, the 2,5-*trans* configuration was also confirmed when α -methyl substituted imino ester 11 was used (Figure 3-6, right).

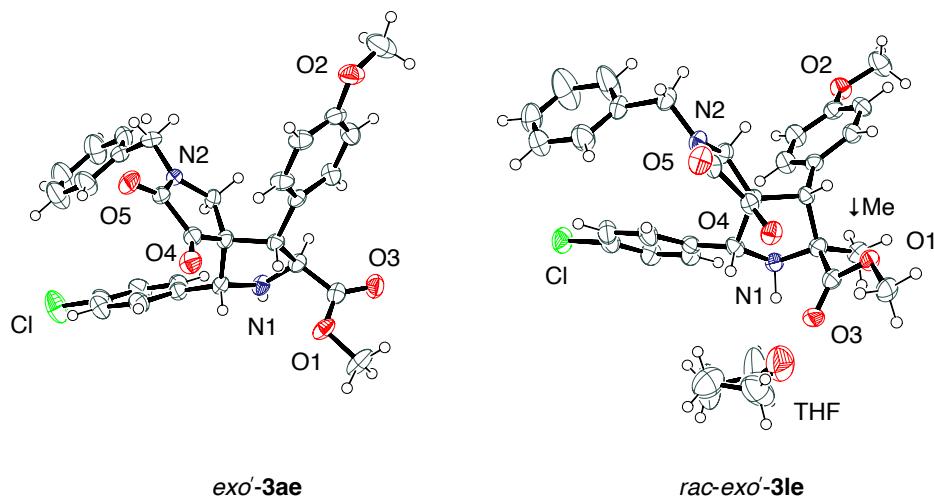

Figure 3-6. ORTEP drawing of 2,5-*trans* spiropyrrolidines.

Based on the results of the control experiments, X-ray analysis, and previous reports,^{6c,12} the author proposed a plausible reaction mechanism (Figure 3-7). The unusual stereochemistry of the 2,5-*trans* diastereomer is accessible by a stepwise addition/cyclization with bond rotation instead of a common concerted 1,3-DC. First, Michael addition of azomethine ylide A generated by a silver catalyst to ylidene-2,3-

dioxopyrrolidines **2** takes place. The nucleophilic addition proceeds from the *si*-face of azomethine ylides **A** to the *si*-face of the 2,3-dioxopyrrolidine **2** in an anti-selective manner, and would be controlled by the interaction between the oxygen functionality of 2,3-dioxopyrrolidine **2** and the silver center (Figure 3-7, B). Although a strained intermediate giving the *endo*-adduct is generated temporarily, it is smoothly converted to intermediate **C** whose 2,3-dioxo functionality coordinates to the silver center. Before the subsequent intramolecular Mannich reaction, the C–N single bond rotates to provide the most stable transition state **D** for giving the *exo'*-adducts. Finally, the silver catalyst is regenerated as soon as the Mannich reaction takes place and affords the desired *exo'*-adducts. The metal-catalyzed stepwise (3+2) cycloaddition of azomethine ylides with electron-deficient olefins for the *exo'*-cycloadduct have been limited to only a few examples using chiral nickel- or copper-complex catalysts.^{6c,12} Therefore, this is the first example of a silver-catalyzed *exo'*-selective asymmetric (3+2) cycloaddition.

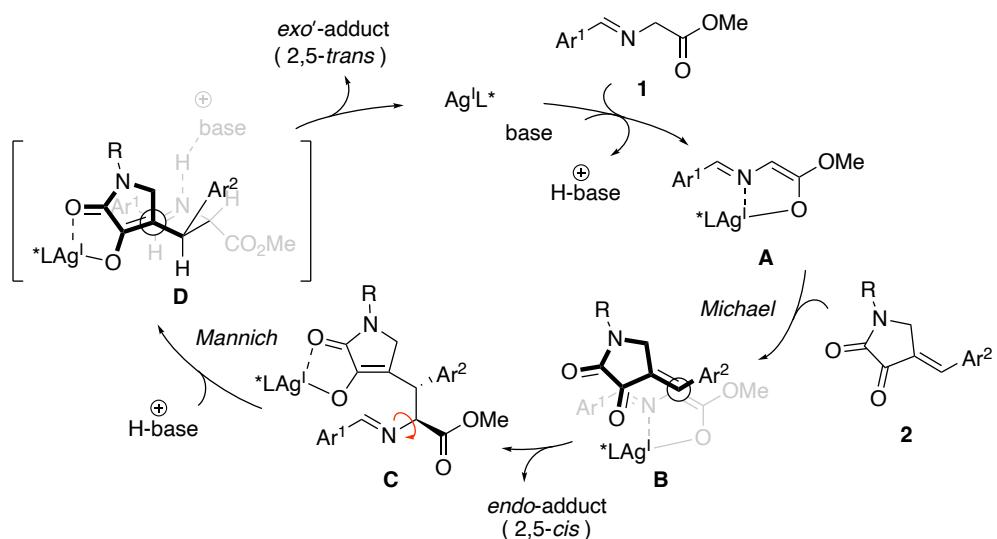

Figure 3-7. Postulated mechanism for *exo'*-selective asymmetric (3+2) cycloaddition of imino esters **1** with ylidene-2,3-dioxopyrrolidines **2**.

To gain insight into the stereochemistry at the 5-position of the pyrrolidine ring, DFT calculations of the intramolecular Mannich reaction were performed based on the possible reaction mechanism shown in Figure 3-7.¹⁵ The AgOAc/PPh₃ complex was selected as the catalyst in this computational study because the 2,5-*trans* selective reaction also proceeded under this condition.

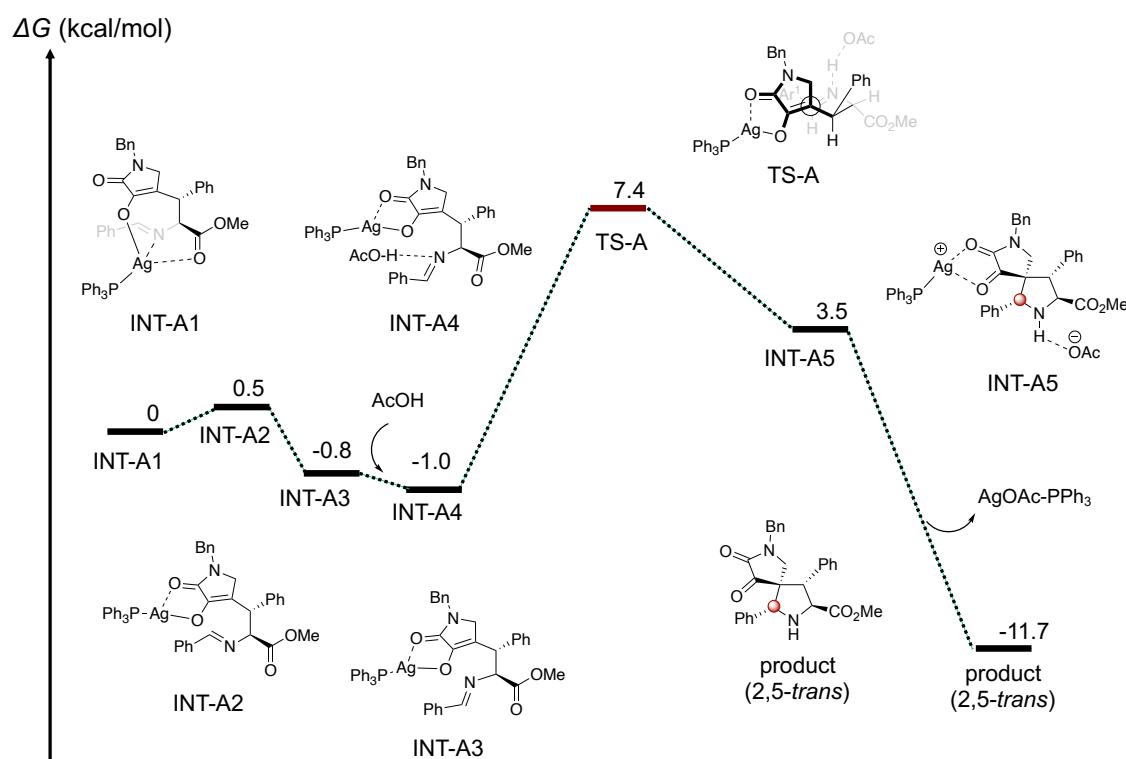

Figure 3-8. The postulated mechanism for the Mannich reaction giving the *exo'*-(2,5-*trans*) adducts under the AgOAc/PPh₃-catalyzed condition (route A). The DFT calculations were carried out at B3PW91/LanL2DZ(Ag)+6-31G*(other atoms) with gd3bj level of theory.

Firstly, the Michael adducts **INT-A1** produced by the Michael addition reaction, the intermediate **INT-A2** whose diketone moiety coordinated to the silver center and the intermediate **INT-A3**, which is produced by the C–N bond rotation of the intermediate **INT-A2** were calculated (Figure 3-8, route A). As a result, it was found that there was little energy difference between each intermediate **INT-A1-3**. Although transition states should exist between each intermediate, they were not calculated due to occurring more

easily than Mannich cyclization in general. The Mannich reaction is proposed to proceed by the action of acetic acid present as a conjugate acid on this intermediate **INT-A3**, and the Gibbs activation energy of the transition state **TS-A** was calculated to be 8.4 kcal/mol.

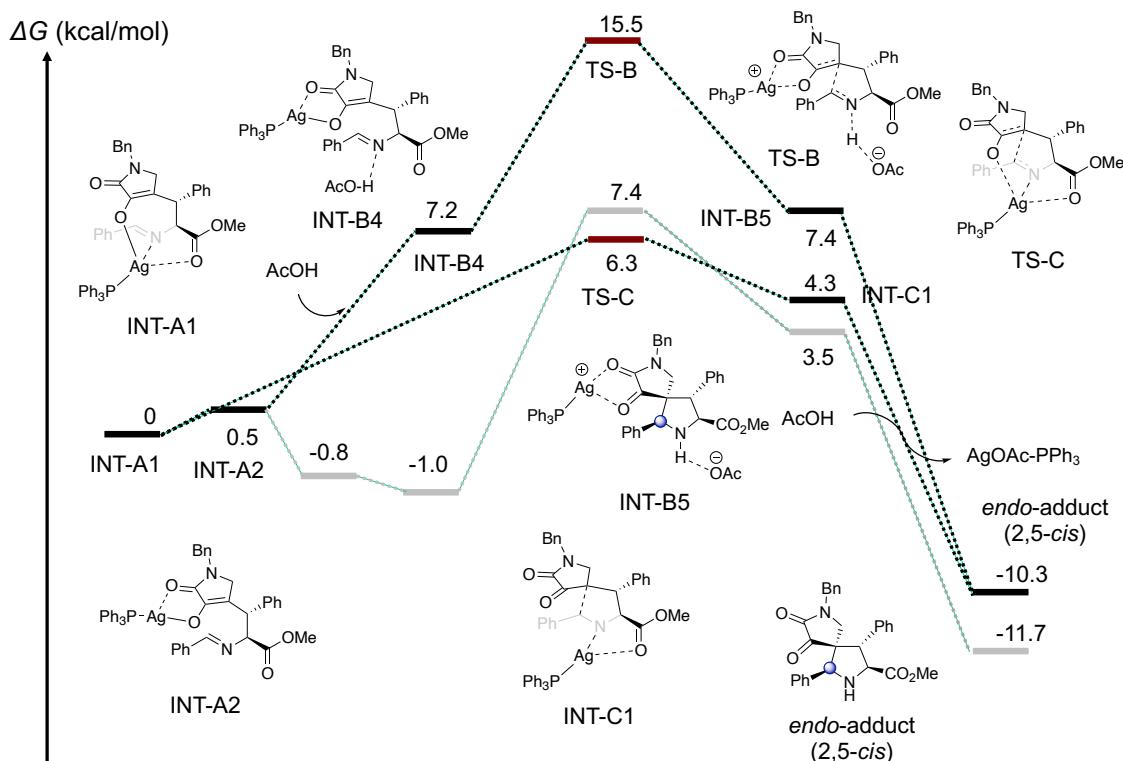

Figure 3-9. The possible mechanism for the Mannich reaction giving the *endo*-(2,5-*cis*) adducts under the AgOAc/PPh₃-catalyzed condition (route B and C). The DFT calculations were carried out at B3PW91/LanL2DZ(Ag)+6-31G*(other atoms) with gd3bj level of theory.

The mechanism for the Mannich reaction which gives *endo*-(2,5-*cis*) adducts was next examined (Figure 3-9, route B). The stability of the intermediate **INT-B4**, in which acetic acid acts on the imine moiety of the intermediate **INT-A2**, was calculated to be 7.2 kcal/mol, indicating that it is unstable compared to the corresponding **INT-A4** ($\Delta G = -1.0$ kcal/mol). The Gibbs activation energy of the transition state **TS-B**, in which the Mannich reaction occurs via the intermediate **INT-B4**, was calculated to be 8.3 kcal/mol. In other words, the formation of intermediate **INT-B4** is thermodynamically unfavorable, and the activation energy of the C–C bond formation process is larger than that of **TS-A**.

Therefore, the formation of the *endo*-adduct by this route B is unacceptable.

However, the *endo*-adduct can be formed by the intramolecular direct Mannich reaction of the Michael adduct **INT-A1** (Figure 3-9, route C). The transition state **TS-C**, where the Mannich reaction occurs directly from the intermediate **INT-A1**, was calculated to be 6.3 kcal/mol, which is slightly lower than the $\Delta G = 7.4$ kcal/mol for the **TS-A** when the *exo'*-adduct is formed. This suggests that the Mannich reaction from the intermediate **INT-A1** via the transition state **TS-C** is kinetically advantageous. Thus, although the formation of the intermediates **INT-A2-4** for leading to the 2,5-*trans* adduct is possible to be thermodynamically favored, it cannot be concluded that the pathway for the 2,5-*trans* adduct is more favorable than that for the 2,5-*cis* adduct only by the result of this calculation study.

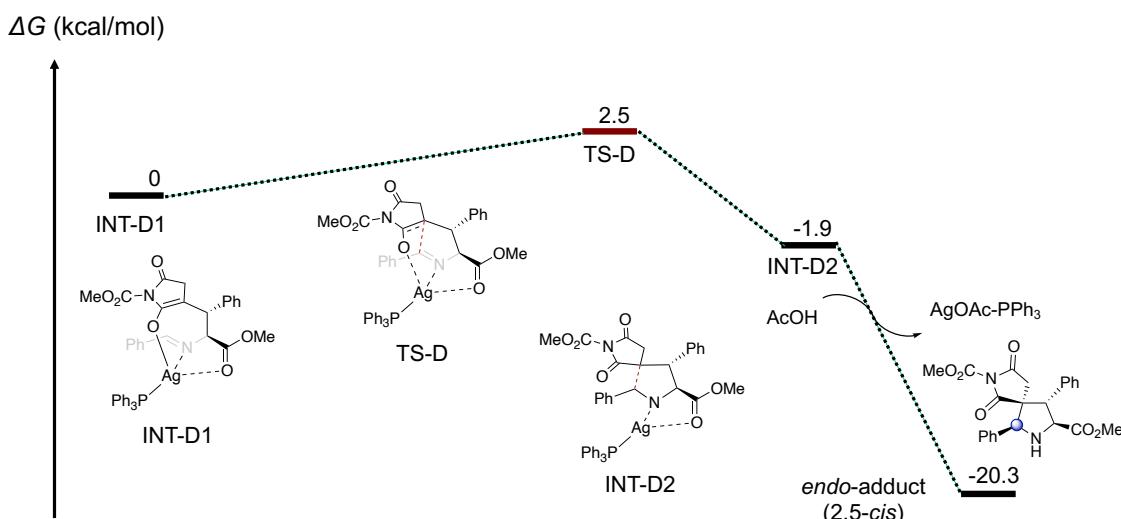

Figure 3-10. The mechanism for the Mannich reaction giving the *endo*-(2,5-*cis*) adducts under the AgOAc/PPh₃-catalyzed condition (route D). The DFT calculations were carried out at B3PW91/LanL2DZ(Ag)+6-31G*(other atoms) with gd3bj level of theory.

On the other hand, the (3+2) cycloaddition using ylidene-succinimides whose structures are similar to ylidene-2,3-dioxopyrrolidines has been reported to afford *endo*-diastereomers (Figure 3-2a).⁹ We also reported that the silver-catalyzed reaction of imino esters with ylidene-succinimides proceeds with the same *endo*-selectivities.¹⁶ Based on the results, the DFT calculation of the reaction using N-CO₂Me-substituted ylidene-

succinimides as the activated olefins was also performed for comparison with the reaction using ylidene-2,3-dioxopyrrolidines.

First, the reaction pathway for the formation of the *endo*-adduct by the Mannich reaction directly from the Michael adduct **INT-D1** was calculated (Figure 3-10, route D). As a result, the activation energy of the transition state **TS-D** was estimated to be $\Delta G = 2.5$ kcal/mol, which is lower than that of the reaction using ylidene-2,3-dioxopyrrolidines (**TS-C**).

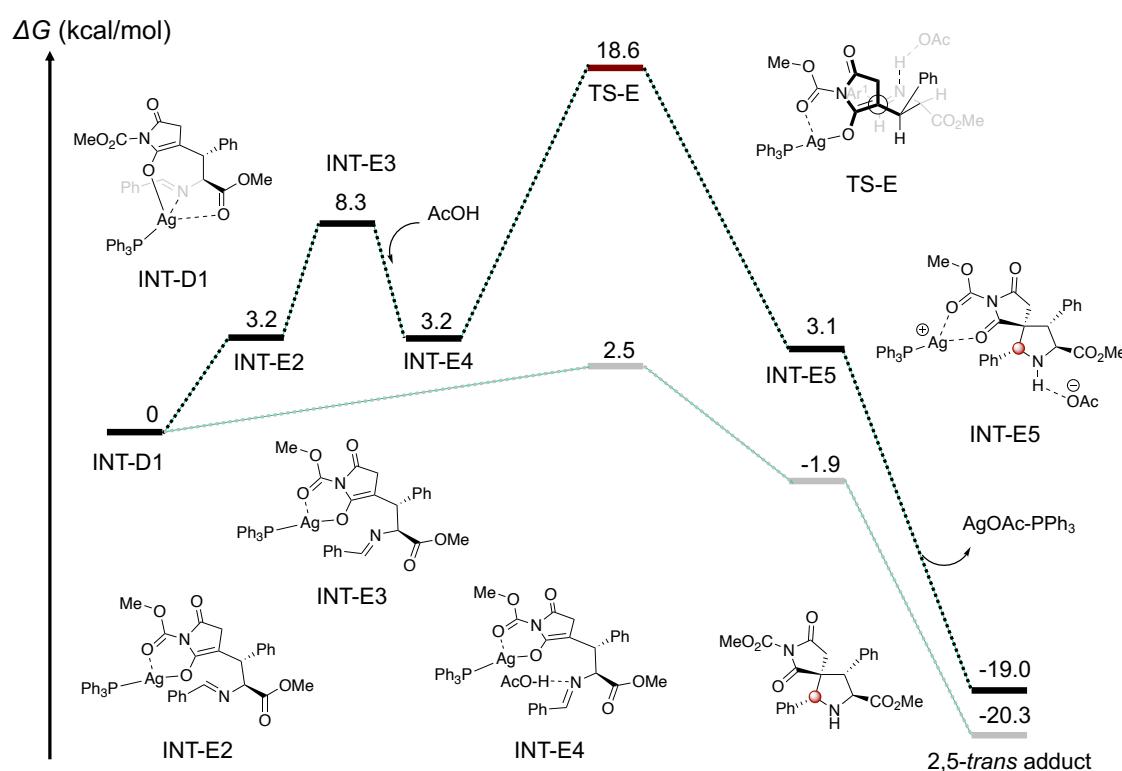

Figure 3-11. The mechanism for the Mannich reaction giving the *exo'*-(2,5-*trans*) adducts under the $\text{AgOAc}/\text{PPh}_3$ -catalyzed condition (route E). The DFT calculations were carried out at B3PW91/LanL2DZ(Ag)+6-31G*(other atoms) with gd3bj level of theory.

The author next analyzed the reaction pathway similar to that shown in Figure 3-8 for giving the 2,5-*trans* adduct via the further intermediates (Figure 3-11). After the Michael adduct **INT-D1** was generated, intermediate **INT-E2** would be formed by the silver catalyst flip to the succinimide moiety. The energy of the intermediate **INT-E2** was calculated to be $\Delta G = 3.2$ kcal/mol and that of the intermediate **INT-E3**, in which the

C–N bond derived from the imino ester is rotated, was calculated to be $\Delta G = 8.3$ kcal/mol. The intermediate **INT-E4**, in which acetic acid acts on the intermediate **INT-E3**, was calculated to be $\Delta G = 3.2$ kcal/mol, and the activation energy of the Mannich reaction from this intermediate **INT-E4** as a starting material was calculated to be 15.4 kcal/mol (**TS-E**). Therefore, the formation of the intermediates **INT-E2-4** is thermodynamically unfavorable in the reaction using ylidene-succinimides, and a very high activation energy of the transition state **TS-E** is required compared to **TS-D** giving *endo*-adduct. These results supported that the silver complex catalyzed (3+2) cycloaddition using ylidene-succinimide as the activated olefins proceed with high *endo*-diastereoselectivity, not giving 2,5-*trans* adducts.

Thus, the above computational studies suggest that the formation of thermodynamically stable intermediates before the Mannich reaction and the activation energy which is equivalent to kinetically favorable *cis*-selective cyclization would be needed to obtain pyrrolidines with a 2,5-*trans* configuration. However, further calculation studies that consider the solvent effect and applying chiral ligand, are necessary because it could not be concluded that the 2,5-*trans* selective Mannich reaction is more favorable than the 2,5-*cis* selective one in the reaction using ylidene-2,3-dioxopyrrolidines.

3-3. Conclusion

In conclusion, the author developed a catalytic asymmetric (3+2) cycloaddition of imino esters with ylidene-2,3-dioxopyrrolidines. The reaction proceeded with unusual 2,5-*trans* diastereoselectivities, and the 2,5-*trans* cycloadducts were obtained with excellent enantioselectivity when our original Ag/TCF complex was used. Additionally, a wide range of imino esters and ylidene-2,3-dioxopyrrolidines could be applied to the reaction, giving various spiropyrrolidines with high yield and excellent stereoselectivity. Control experiments suggested that the 2,5-diastereoselectivity was not due to a common 2,5-*cis* selective cycloaddition and subsequent epimerization, i.e., a stepwise Michael addition/Mannich reaction was proposed as a reasonable pathway.

3–4. Experimental Section

The general information was described in the Experimental Section of Chapter 2.

Unless otherwise stated, all reactions were carried out with oven-dried glassware under the atmosphere of nitrogen. Starting materials, ylidene-2,3-dioxopyrrolidines **2** were prepared and identified by reported methods.¹⁷ Racemic products of **3** were prepared using PPh₃ (5.5 mol%) as the ligand. All other chemical reagents used commercial grade and used as received.

Silver-Catalyzed *exo'*-Selective Asymmetric (3+2) Cycloaddition of Imino Esters **1 with Ylidene-2,3-dioxopyrrolidines **2**.** A mixture of AgOCOCF₃ (2.2 mg, 10 µmol, 5.0 mol%) and (*R*, *S_p*)-ThioClickFerrophos **L1** (6.9 mg, 11 µmol, 5.5 mol%) were dissolved in dry THF (1.0 mL) at room temperature and stirred for 30 minutes at the same temperature. After the reaction mixture was cooled to 0°C, to the mixture were added *p*-chloro phenyl imino esters **1a** (46.4 mg, 0.22 mmol, 1.10 equiv.), ylidene-2,3-dioxopyrrolidines **2a** (55.5 mg, 0.20 mmol, 1.0 equiv.), and Et₃N (5.6 µL, 40 µmol, 20 mol%). After stirring for 16 h at 0°C, the mixture was diluted with 30 mL EtOAc, filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude mixture showed that the *exo'*-adduct is the sole product. The residue was purified by silica gel column chromatography (20 g, toluene/EtOAc/acetone = 10/1/1) to give methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-chlorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-**3aa**) (89.0 mg, 0.182, 91% yield, >99% dr, 96% ee) as a pale yellow solid.

2 mmol Scale Preparation of methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-chlorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-3aa**).** A mixture of AgOCOCF₃ (22.1 mg, 0.01 mmol, 5.0 mol%) and (*R*, *S_p*)-ThioClickFerrophos **L1** (69.3 mg, 0.11 mmol, 5.5 mol%) were dissolved in dry THF (10.0 mL) at room temperature and stirred for 30 minutes at the same temperature. After the reaction mixture was cooled to 0°C, to the mixture were added imino esters **1a** (466 mg, 2.20 mmol, 1.10 equiv.),

ylidene-2,3-dioxopyrrolidine **2a** (555 mg, 2.00 mmol, 1.00 equiv.), and Et₃N (55.4 μL, 0.397 mmol, 19.9 mol%). After stirring for 16 h at 0°C, the mixture was diluted with 60 mL EtOAc, filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude mixture showed that the *exo'*-adduct is the sole product. The residue was purified by silica gel column chromatography (50 g, toluene/EtOAc/acetone = 10/1/1) to give methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-chlorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-**3aa**) (889 mg, 1.82 mmol, 90.8% yield, >99% dr, 96% ee) as a pale yellow solid.

Control Experiment: Reaction of α-Methyl-substituted Imino Ester **1l with Ylidene-2,3-dioxopyrrolidine **2e**.** A mixture of AgOCOCF₃ (2.2 mg, 10 μmol, 5.0 mol%) and (*R*, *S_p*)-ThioClickFerrophos **L1** (6.9 mg, 11 μmol, 5.5 mol%) were dissolved in dry THF (1.0 mL) at room temperature. After stirring for 30 minutes at the same temperature, to the mixture were successively added α-substituted imino esters **1l** (49.6 mg, 0.22 mmol, 1.10 equiv.), ylidene-2,3-dioxopyrrolidines **2e** (61.5 mg, 0.20 mmol, 1.0 equiv.), and Et₃N (5.6 μL, 40 μmol, 20 mol%). After stirring for 16 h at room temperature, the mixture was diluted with 30 mL EtOAc, filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude mixture showed that the *exo'*-adduct is the sole product. The residue was purified by silica gel column chromatography (20 g, toluene/EtOAc/acetone = 10/1/1) to give methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-chlorophenyl)-4-(4-methoxyphenyl)-3-methyl-8,9-dioxo-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-**3le**) (77.0 mg, 0.145 mmol, 72.2%, > 99% dr, 81% ee) as a pale yellow solid.

Control Experiment: Reaction of Deuterium-labeled Imino Ester **1m with Ylidene-2,3-dioxopyrrolidine **2a**.** A mixture of AgOCOCF₃ (2.2 mg, 10 μmol, 5.0 mol%) and (*R*, *S_p*)-ThioClickFerrophos **L1** (6.9 mg, 11 μmol, 5.5 mol%) were dissolved in dry THF (1.0 mL) at room temperature and stirred for 30 minutes at the same temperature. After the reaction mixture was cooled to 0°C, to the mixture were added deuterium-labeled imino esters **1m-d** (39.2 mg, 0.22 mmol, 1.10 equiv.), ylidene-2,3-dioxopyrrolidines **2a** (55.5

mg, 0.20 mmol, 1.0 equiv.), and Et₃N (5.6 μL, 40 μmol, 20 mol%). After stirring for 16 h at 0°C, the mixture was diluted with 30 mL EtOAc, filtered through a short Celite pad, and concentrated under reduced pressure. ¹H NMR analysis of the crude mixture showed that the *exo'*-adduct is the sole product. The residue was purified by silica gel column chromatography (20 g, toluene/EtOAc/acetone = 10/1/1) to give methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-8,9-dioxo-1,4-diphenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate-1-*d* (*exo'*-3ma-*d*) (79.2 mg, 0.174 mmol, 86.9%, >99% dr, 98% ee) as a pale yellow solid.

Methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-chlorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-3aa). (89.0 mg, 90.9%, >99% dr, 96% ee); pale yellow solid; mp 147–149 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.27–7.30 (m, 3H), 7.21–7.23 (m, 1H), 7.10–7.16 (m, 8H), 6.52–6.57 (m, 2H), 4.95 (s, 1H), 4.32–4.38 (m, 3H), 3.92 (d, 1H, *J* = 14.6 Hz), 3.70 (s, 3H), 3.16 (s, 2H); ¹³C NMR (101 MHz, CDCl₃): δ 202.4, 174.6, 158.8, 134.89, 134.86, 134.3, 133.6, 129.2, 129.0, 128.9, 128.3, 127.9, 127.8, 127.73, 127.70, 69.3, 59.8, 58.1, 56.8, 52.9, 48.2, 43.7; HPLC (Daicel Chiraldapak IH-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 254 nm); *t*_R = 24.0 min (minor), 37.7 min (major); [α]_D²⁵ 26.92 (*c* 0.06, CHCl₃); HRMS (ESI) *m/z*: [M+Na]⁺ Calcd for C₂₈H₂₅³⁵ClN₂NaO₄⁺, 511.1395; found 511.1375.

Methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-fluorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (*exo'*-3ba). (87.4 mg, 92.4%, >99% dr, 96% ee); pale yellow solid; mp 145–150 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.27–7.30 (m, 3H), 7.09–7.22 (m, 7 H), 6.84–6.89 (m, 2H), 6.56 (m, 2H), 4.97 (s, 1H), 4.42 (d, 1H, *J* = 8.8 Hz), 4.33 (d, 1H, *J* = 8.8 Hz), 4.29 (d, 1H, *J* = 14.6 Hz), 3.96 (d, 1H, *J* = 14.6 Hz), 3.71 (s, 3H), 3.23 (d, 1H, *J* = 11.9 Hz), 3.18 (d, 1H, *J* = 11.9 Hz); ¹³C NMR (101 MHz, CDCl₃): δ 202.4, 174.6, 162.6 (d, *J*_{C-F} = 247 Hz), 158.8, 135.0, 133.7, 131.9 (d, *J*_{C-F} = 3.1 Hz), 129.2, 128.9, 128.3, 128.0 (d, *J*_{C-F} = 8.2 Hz), 127.9, 127.8, 127.7, 115.7 (d, *J*_{C-F} = 21.5 Hz), 69.3, 59.8, 58.28+58.27 (rotamer), 56.7, 52.9, 48.2, 43.7; HPLC (Daicel Chiraldapak IH-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 254 nm); *t*_R = 25.5 min (minor), 38.4 min (major); [α]_D²⁵ 59.61 (*c* 0.06, CHCl₃); HRMS (ESI) *m/z*: [M+Na]⁺ Calcd for

$C_{28}H_{25}FN_2NaO_4^+$, 495.1691; found 495.1679.

Methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(4-bromophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (exo'-3ca). (90.2 mg, 84.5%, >99% dr, 92% ee); pale yellow solid; mp 145–147 °C; 1H NMR (400 MHz, $CDCl_3$): δ 7.28–7.33 (m, 5H), 7.22–7.23 (m, 1H), 7.13–7.17 (m, 4H), 7.08–7.13 (m, 2H), 6.56 (d, 2H, J = 7.0 Hz), 4.96 (s, 1H), 4.47 (d, 1H, J = 8.9 Hz), 4.35 (d, 1H, J = 14.6 Hz), 4.33 (d, 1H, J = 8.9 Hz), 3.93 (d, 1H, J = 14.6 Hz), 3.71 (s, 3H), 3.25 (d, 1H, J = 12.0 Hz), 3.21 (d, 1H, J = 12.0 Hz); ^{13}C NMR (101 MHz, $CDCl_3$): δ 202.3, 174.6, 158.8, 135.4, 134.9, 133.6, 132.0, 129.2, 129.0, 128.4, 128.1, 128.0, 127.8, 127.7, 122.6, 69.3, 59.8, 58.1, 56.9, 53.0, 48.2, 43.7; HPLC (Daicel Chiralpak IH-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 254 nm); t_R = 26.7 min (minor), 40.8 min (major); $[\alpha]_D^{25}$ 38.64 (*c* 0.05, $CHCl_3$); HRMS (ESI) *m/z*: $[M+H]^+$ Calcd for $C_{28}H_{26}^{79}BrN_2O_4^+$, 533.1070; found 533.1068.

Methyl (1*R*, 3*S*, 4*S*, 5*R*)-7-benzyl-1-(3-chlorophenyl)-8,9-dioxo-4-phenyl-2,7-diazaspiro[4.4]nonane-3-carboxylate (exo'-3da). (66.0 mg, 67.4%, >99% dr, 88% ee); pale yellow solid; mp 157–160 °C; 1H NMR (400 MHz, $CDCl_3$): δ 7.35 (s, 1H), 7.27–7.30 (m, 3H), 7.09–7.22 (m, 7H), 6.95 (d, 1H, J = 7.7 Hz), 6.55 (m, 2H), 4.98 (s, 1H), 4.35 (d, 1H, J = 8.9 Hz), 4.31 (d, 1H, J = 8.9 Hz), 4.24 (d, 1H, J = 14.7 Hz), 4.02 (d, 1H, J = 14.7 Hz), 3.69 (s, 3H), 3.16 (s, 2H); ^{13}C NMR (101 MHz, $CDCl_3$): δ 202.3, 174.5, 158.8, 138.8, 134.9, 134.8, 133.7, 130.1, 129.2, 128.9, 128.8, 128.4, 128.0, 127.8, 127.7, 126.6, 124.8, 69.1, 59.8, 58.1, 57.1, 52.9, 48.2, 43.8; HPLC (Daicel Chiralpak IC-3, *n*-hexane/EtOAc = 70/30, 1.0 mL/min, 254 nm); t_R = 9.3 min (minor), 10.5 min (major); $[\alpha]_D^{25}$ 91.00 (*c* 0.06, $CHCl_3$); HRMS (ESI) *m/z*: $[M+H]^+$ Calcd for $C_{28}H_{26}^{35}ClN_2O_4^+$, 489.1576; found 489.1581.

X-ray Crystallographic Analysis. The crystallographic data of *exo'-3ae* and *rac-exo'-3le* were summarized in Table S3-1. Single crystals of *exo'-3ae* were prepared from CH₂Cl₂/MeCN co-solvent by antisolvent addition technique using *n*-hexane as an antisolvent and single crystals of *rac-exo'-3le* were prepared from tetrahydrofuran by vapor diffusion technique using ethanol as an antisolvent. A suitable single crystal was respectively selected and mounted on the glass fiber and transferred to the goniometer of a Rigaku VariMax Saturn CCD diffractometer with graphite-monochromated MoK α radiation ($\lambda = 71.073$ pm). Yadokari-XG 2009 program was used as a graphical interface. The structure was solved and refined by SIR-2004 by SHELX-97 programs. The refinement was performed anisotropically for all non-hydrogen atoms. Hydrogen atoms were placed using AFIX instructions.

In the case of *rac-exo'-3le*, *CrystalStructure* crystallographic software package was used as a graphical interface. The structure was solved and refined by SHELXS Version 2014/5 and SHLEXL Version 2016/6. The difference Fourier maps has suggested that the voids of each crystal were occupied by tetrahydrofuran molecules, which could not be appropriate because of heavy disorders. The electron density associated with the solvent molecule was removed by SQUEEZE routine of PLATON.

Table S3-1. Crystal data and structure refinements for *exo'-3ae* and *rac-exo'-3le*.

Compound	<i>exo'-3ae</i>	<i>rac-exo'-3le</i>

Computational Study. The molecular geometries for the transition states (TS) and the intermediates (INT) were calculated with the Gaussian 16 software package. The stationary points and the harmonic vibrational frequencies were calculated at B3PW91/LanL2DZ(Ag)+6-31G* level of theory to estimate the Gibbs free energy. All Gibbs free energy values were calculated at 298.15 K, and all transition structures were optimized without constraints. Transition structures show only one negative eigenvalue in their diagonalized force constant matrices, and their associated eigenvectors were confirmed to correspond to the motion along the reaction coordinate. The intrinsic reaction coordinate (IRC) routes were calculated in both directions toward the corresponding minima for each transition-state structure. When the IRC calculations failed to reach the energy minima on the potential energy surface, geometry optimizations were carried out as a continuation of the IRC path.

Table S3-2. Total electronic energies (E, in a.u.), thermal correction to Gibbs free energy (TCGFE, in a.u.), and number of imaginary frequencies (NIMAG) in the Mannich reaction of the Michael adduct formed by the (3+2) cycloaddition of 2,3-dioxopyrrolidine **2** with azomethine ylide derived from imino ester **1** and AgOAc/PPh₃ complex.^a

Chapter 4

**Formal Diastereodivergent Synthesis
of 2,5-*cis/trans*-Pyrrolidines
via Asymmetric (3+2) Cycloaddition**

4–1. Introduction

Stereodivergent synthesis that affords several stereoisomers is of interest in drug discovery because stereodivergency can lead to various biological activities of stereoisomeric compounds.¹ Several useful strategies including those controlled by catalysts, additives, and substrates have been proposed by many research groups in recent years and stereodivergent syntheses with high diastereo- and enantioselectivity have been successful.² However, accessing all stereoisomers that exist theoretically is still difficult.³ For example, asymmetric 1,3-DC is one of the most suitable methods for the divergent preparation of chiral pyrrolidines, which are frequently found in biologically active compounds.⁴ Indeed, *endo/exo*-diastereodivergent synthesis has been well developed by metal- and ligand-controlled strategies. Nonetheless, 2,5-*cis/trans* diastereodivergent synthesis is limited to a few examples^{5,6} because of the difficulty in accessing 2,5-*trans* adducts.^{7,8}

Given this background, the author developed the *exo'*-selective asymmetric (3+2) cycloaddition of imino esters with ylidene-2,3-dioxopyrrolidines.⁹ According to previous work, it was suggested that the unusual 2,5-*trans* diastereoselectivity was expressed when spiropyrrolidines were constructed using ylidene-heterocycles.¹⁰ The author envisioned the establishment of a new stereodivergent synthetic methodology using well-designed activated olefins. Initially, 2,5-*trans* adducts would be generated by the reaction of imino esters with ylidene-heterocycles which are easy to ring-open, and the subsequent ring-opening reaction could convert spirocyclic compounds to acyclic pyrrolidines with the 2,5-*trans* configuration. In contrast to the synthesis of 2,5-*trans* pyrrolidines, 2,5-*cis* pyrrolidines could be obtained by the common metal complex-catalyzed reaction by using acyclic olefins. Thus, the diastereodivergent 2,5-*cis/trans* pyrrolidines could be achieved using different types of activated olefins.

In this work, the author focused on the isoxazolone ring as the heterocycle because it is easy to ring-open.¹¹ The heterocycle smoothly transforms into ketone groups by N–O

bond reduction with decarboxylation.¹² Therefore, the author engaged in the metal complex-catalyzed asymmetric (3+2) cycloaddition using ylidene-isoxazolones which have rarely been employed in the asymmetric (3+2) cycloaddition (Figure 4-1). As a result, the asymmetric (3+2) cycloaddition of imino lactones with ylidene-isoxazolones proceeded with 2,5-*trans* diastereoselectivity. Additionally, the isoxazolone ring could be converted to a ketone group after the construction of the pyrrolidine ring, giving 4-carbonyl group-substituted pyrrolidines in a 2,5-*trans* fashion. The (3+2) cycloaddition using acyclic α,β -unsaturated ketones as the activated olefins afforded the corresponding 2,5-*cis* pyrrolidines with high diastereo- and enantioselectivity.^{13a,14} Thus, the author developed the first diastereodivergent construction of 2,5-*cis/trans*-pyrrolidines by a dipolarophile-controlled strategy. This could become a robust method for the stereodivergent preparation of pyrrolidines in the field of drug discovery because both 2,5-*cis/trans* derivatives are frequently used as biologically active pyrrolidines.¹⁵

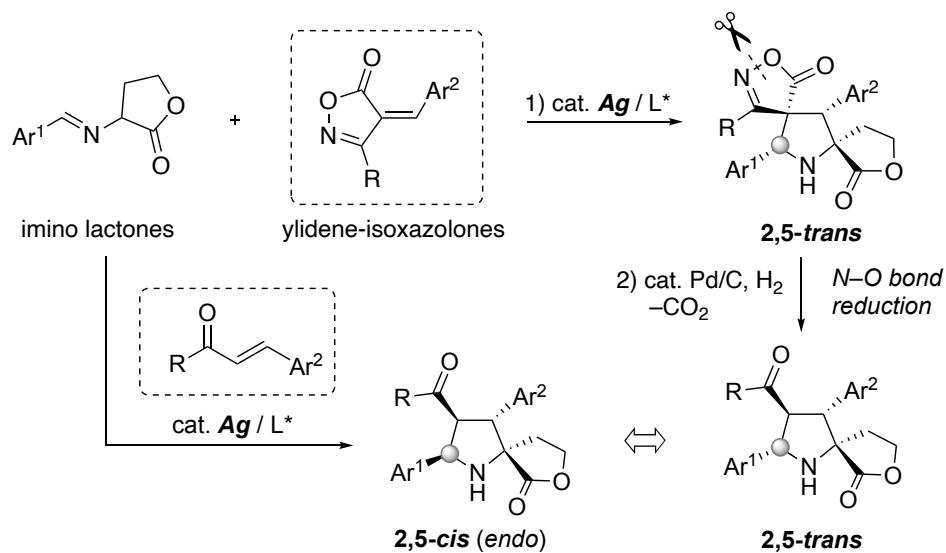

Figure 4-1. This work: dipolarophile-controlled diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines based on asymmetric (3+2) cycloaddition of imino lactones.

4–2. Results and Discussion

The reaction of imino esters with ylidene-isoxazolones **2a** was initially investigated using common copper and silver catalysts under several conditions.⁴ However, the desired cycloadducts were not obtained and complex mixtures resulted. Thus, the author examined some imino ester derivatives as azomethine ylide precursors. As a result of these initial experiments, the (3+2) cycloaddition of imino lactones **1a** with ylidene-isoxazolones **2a** proceeded efficiently in the presence of AgOAc (5.0 mol%), (*S, S_p*)-*iPr*-FcPHOX **L1** (5.5 mol%), Et₃N (20 mol%), and 3 Å MS (200 mg) in CH₂Cl₂ at room temperature. ¹H NMR analysis of the crude product revealed that a single diastereomer was generated and the corresponding cycloadducts were successfully isolated in 86% yield and 65% ee by column chromatography (Table 4-1, entry 1). X-ray crystallographic analysis disclosed that the desired 2,5-*trans* cycloadducts were obtained, whose carbonyl groups at the 2-position of the pyrrolidine ring were placed *trans* to aryl groups at the 5-position (details of the stereochemistry are described below and in Figure 4-4.).

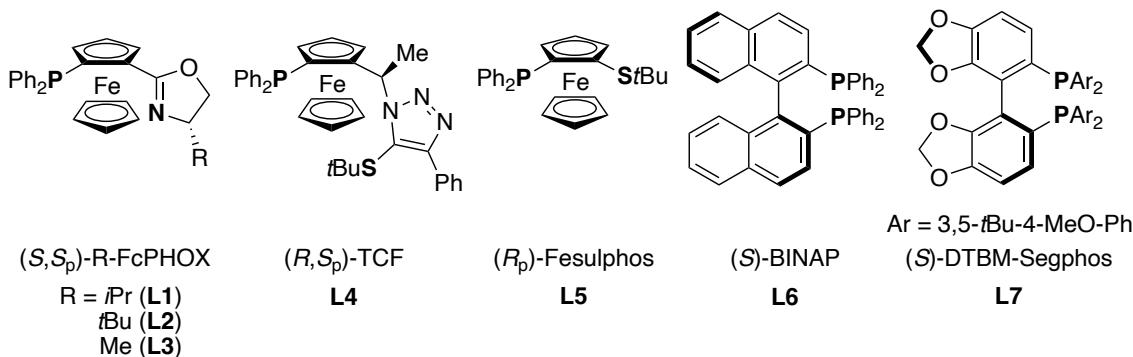

Figure 4-2. Chiral ligands employed in this study.

Screening of chiral copper and silver complexes was next carried out using several ligands (Figure 4-2), and the results are summarized in Table 4-1. Although high enantioselectivity was achieved when *iPr*-FcPHOX **L1** was applied to the asymmetric (3+2) cycloaddition, other FcPHOX derivatives **L2** and **L3** resulted in moderate enantioselectivity (entries 1-3). When our original ligand TCF **L4** was used under the

Table 4-1. Screening of chiral copper and silver complex^a

The reaction scheme illustrates the asymmetric cycloaddition of imino lactone **1a** (Ar¹ = *p*-ClC₆H₄, 1.1 equiv.) and ylidene-isoxazolone **2a** (0.20 mmol) in the presence of a chiral metal / ligand catalyst (5 mol%), triethylamine (20 mol%), and 3 Å MS in CH₂Cl₂ at room temperature for 16 h. The product **3aa** (2,5-*trans*) is shown with its stereochemistry.

[a] Condition: **1a** (0.22 mmol), **2a** (0.20 mmol), metal salt (5.0 mol%), ligand (5.5 mol%), Et₃N (20 mol%), CH₂Cl₂ (1.0 mL), 3 Å MS (200 mg), rt, 16 h. [b] Isolated yield. [c] Determined by crude ¹H NMR. [d] Determined by chiral HPLC (Daicel Chiralpak ID-3).

silver-catalyzed condition, the product was obtained in high yield, but the enantioselectivity was not improved (entry 4). Other chiral ligands such as Fesulphos **L5**, BINAP **L6**, and DTBM-Segphos **L7** were not as effective for the asymmetric reaction, and low enantioselectivity resulted (entries 5-7). In addition, copper complex-catalyzed systems were unsuitable for the reaction of imino lactones **1a** with ylidene-isoxazolones **2a**, with significantly decreased yield and stereoselectivity (entries 8-12). Therefore, the author conducted further examinations to improve the enantioselectivity by using a silver/

iPr-FcPHOX complex catalyst.

The reaction conditions were first optimized (Table 4-2). When several solvents such as THF, Et₂O, toluene, MTBE, and CPME were applied to the reaction, ether-based solvents tended to give higher enantioselectivity (entries 1-5). Et₂O was chosen as the most suitable solvent for the reaction, and the enantioselectivity increased to 80% ee

[a] Condition: **1a** (0.22 mmol), **2a** (0.20 mmol), metal salt (5.0 mol%), (S, S_p) -FcPHOX **L1** (5.5 mol%), base (20 mol%), solvent (1.0 mL), 3 Å MS (200 mg), rt, 16 h. [b] Isolated yield. [c] Determined by chiral HPLC (Daicel Chiralpak ID-3). [d] Conducted at 0°C. [e] 1.5 equiv. of **1a** was used. [f] Determined by using Daicel Chialpak AD-H instead of ID-3.

(entry 2). Screening of additives (entries 6-9) revealed that the reaction smoothly proceeded without the addition of bases, and the enantioselectivity was improved to 88% ee (entry 9). Other silver salts such as AgOTf and AgOCOCF₃ were examined (entries 10, 11), and using AgOCOCF₃ increased the yield to 82% (entry 11). Although the yield decreased when the reaction was carried out at 0 °C (entry 12), the yield was improved to 93% with high enantioselectivity when 1.5 equivalents of imino lactones **1a** were used (entry 13).

The scope of imino lactones **1** was investigated under the optimal conditions (Table 4-2, entry 13), and a variety of substrates was successfully applied to the 2,5-*trans* selective asymmetric (3+2) cycloaddition (Figure 4-3). Imino lactones bearing a halogen atom at *para*- and *meta*-positions reacted with ylidene-isoxazolone **2a**, giving the corresponding products **3ba** and **3ca**, respectively. The reaction using imino lactones bearing no substituent on the aryl groups **1d** also yielded the cycloadducts **3da** with high enantioselectivity. Although the *ortho*-methyl substrate **3ea** was produced in moderate yield, the enantioselectivity remained high. Neither *meta*- nor *para*-methyl substituents had much effect on the yield or stereoselectivity, giving the products **3fa** and **3ga**, respectively. The reaction using strong electron-withdrawing groups such as *para*-CF₃ substituted imino lactones **1h** resulted in good yield and high enantioselectivity. A strong electron-donating substituent such as the *para*-MeO group decreased the yield, but had high enantioselectivity. The cycloadduct substituted 2-thienyl group **3ja** was obtained quantitatively in 86% enantiomeric excess. Therefore, some substituents on the aryl group of imino lactones affected the yield, but in most cases, the diastereo- and enantioselectivity remained high.

The substrate scope of ylidene-isoxazolones **2** was examined under the optimized reaction conditions (Figure 4-4). A *para*-substituent on the aryl group of the isoxazolones **2** did not affect the yield or stereoselectivity, giving the *para*-chloro, -bromo, and -methoxy substituted products **3ab-ad**, respectively. The position of the substituent had

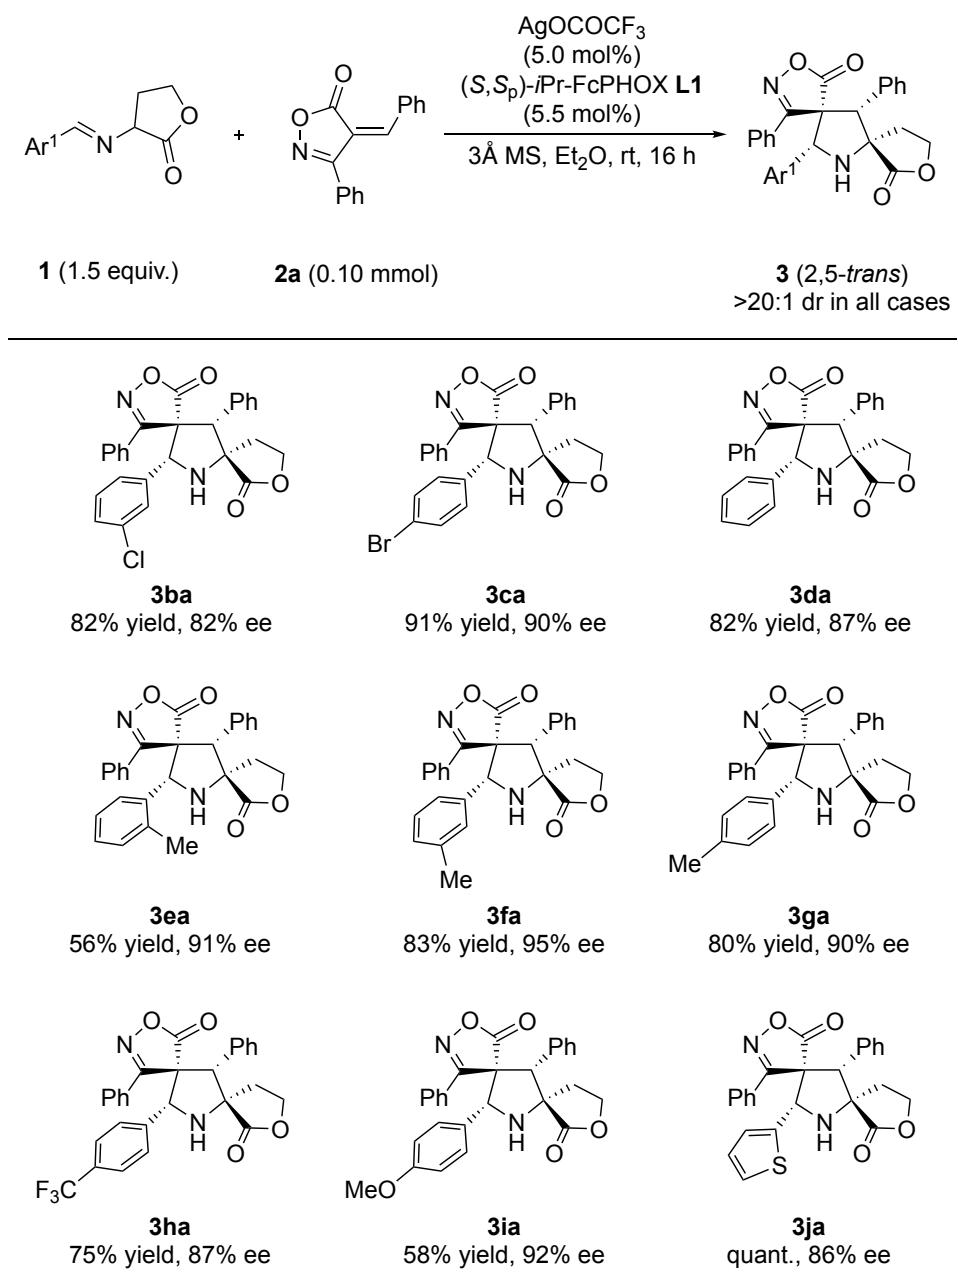

Figure 4-3. Scope of imino lactones **1**.

little impact on the reactivity and stereoselectivity, so the cycloadducts bearing a methyl group at *ortho*-, *meta*-, and *para*-positions **3ae-ag** were obtained efficiently. A 2-thienyl group could be introduced into the 3-position of the pyrrolidine ring with high enantioselectivity. However, a different substituent at the 3-position of the isoxazolone ring affected the enantioselectivity, i.e., *iPr*-substituted cycloadduct **3ai** was produced in only 59% ee. However, 3-methyl substrates generated the corresponding cycloadducts

3aj, 3dj, and 3ak with high enantioselectivity.

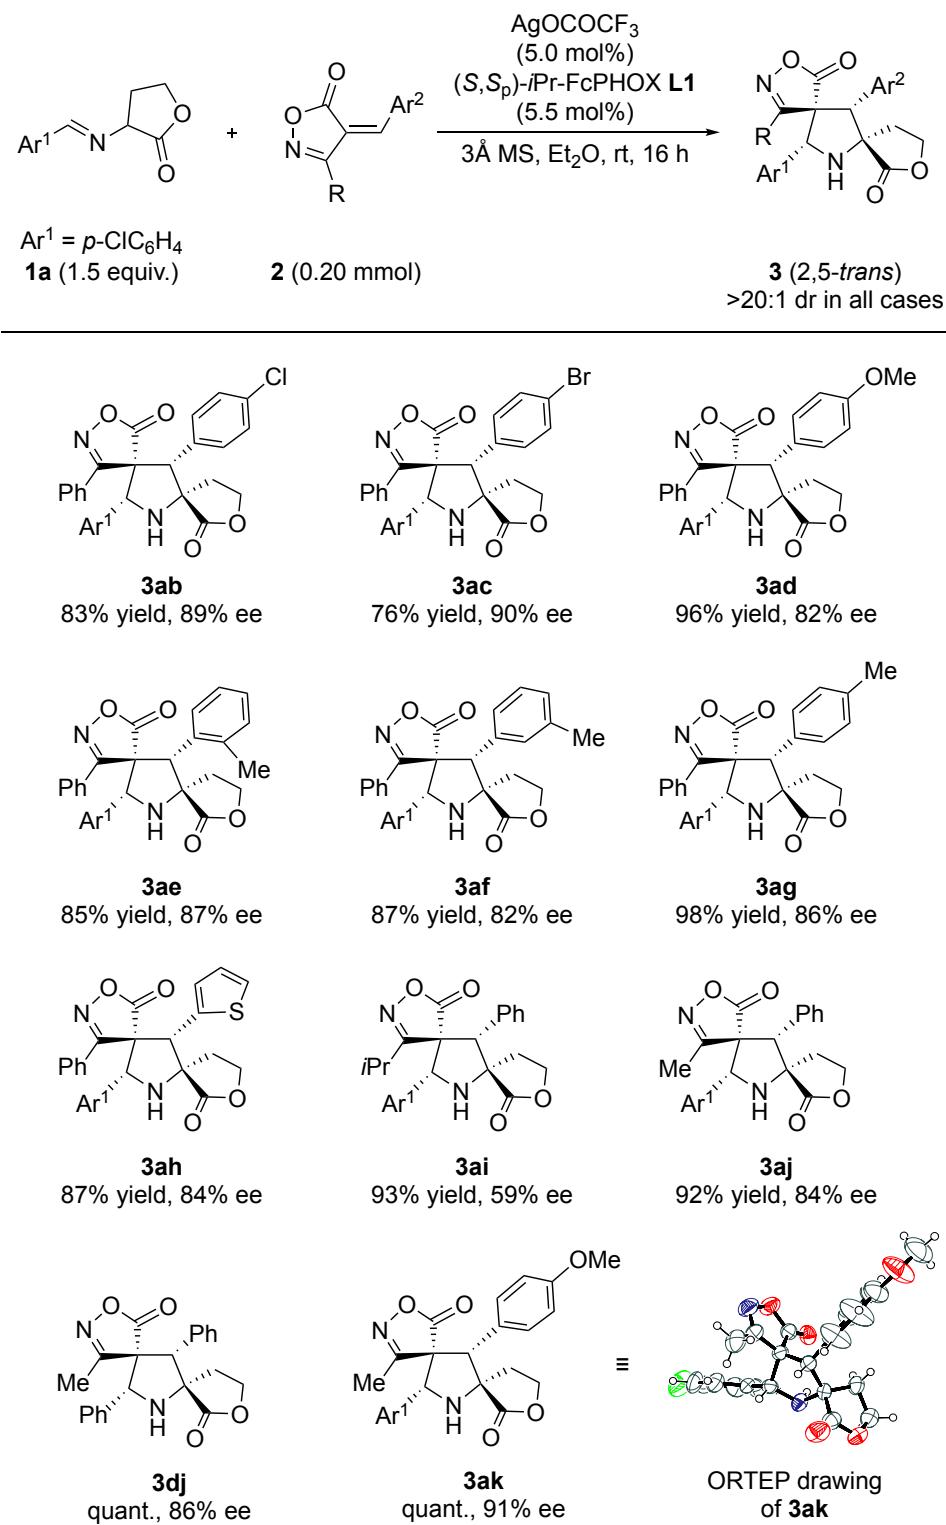

Figure 4-4. Scope of ylidene-isoxazolones **2**.

A single crystal of the product **3ak** was suitable for X-ray crystallographic analysis, in which the stereochemistry could be determined. The stereocenters at the 2- and 5-positions of the pyrrolidine ring were respectively determined as *S* and *R*. The relationship of the carbonyl group at the 2-position and the *para*-chloro phenyl group at the 5-position was *trans*. The stereocenters at the 3- and 4-positions of the pyrrolidine ring, which were derived from the ylidene-isoxazolone **2**, were detected as *S* and *R*, respectively.

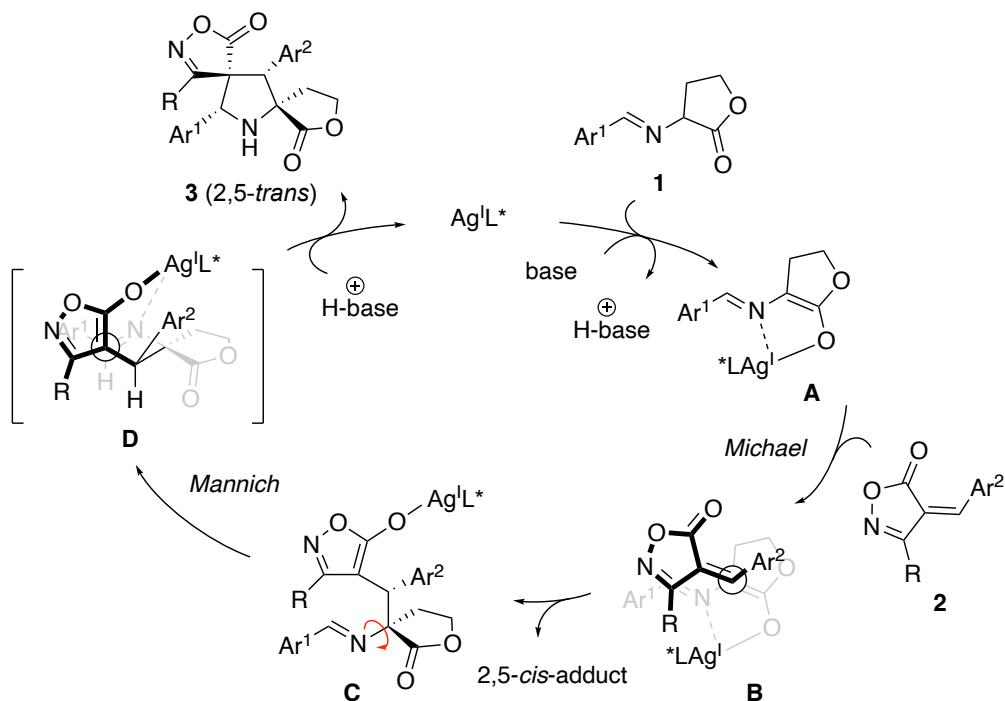

Figure 4-5. Postulated mechanism for asymmetric *2,5-trans* selective (3+2) cycloaddition of imino lactones **1** with ylidene-isoxazolones **2**.

According to some previous reports,^{5,7,9} the unusual *2,5-trans* selective (3+2) cycloaddition would proceed via a stepwise Michael addition/Mannich reaction with bond rotation (Figure 4-5). First, azomethine ylides **A** are generated by the action of the silver complex on imino lactones **1**, and azomethine ylides **A** smoothly react with activated olefins **2**. At this time, a suitable transition state **B** is proposed, i.e., the asymmetric Michael addition takes place from the *si*-face of azomethine ylides **A** to the *si*-face of the ylidene-isoxazolones **2**. Simultaneously, the silver complex flips to the isoxazolone moiety, giving the isoxazole intermediate **C** that is stabilized by the formation

of the heteroaromatic ring. After C–N bond rotation, the intramolecular Mannich reaction proceeds via the postulated transition state **D** to afford the 2,5-*trans* products as the major product. If the Mannich reaction immediately took place after the first bond formation, the 2,5-*cis* cycloadducts should be obtained as the major diastereomer. However, the direct cyclization before the C–N bond rotation is unfavorable due to high steric constraints. Therefore, the unusual 2,5-*trans* diastereoselectivity would be guided by ylidene-isoxazolones **2**.

Based on the postulated reaction pathway shown in Figure 4-5, DFT calculations were conducted to gain insight into the mechanism for the 2,5-*trans* selective formation of the pyrrolidine ring (Figure 4-6).¹⁶ Since the 2,5-*trans* diastereoselectivity is also observed when the AgOAc/PPh₃ complex is used, this silver complex was employed in this computational study.

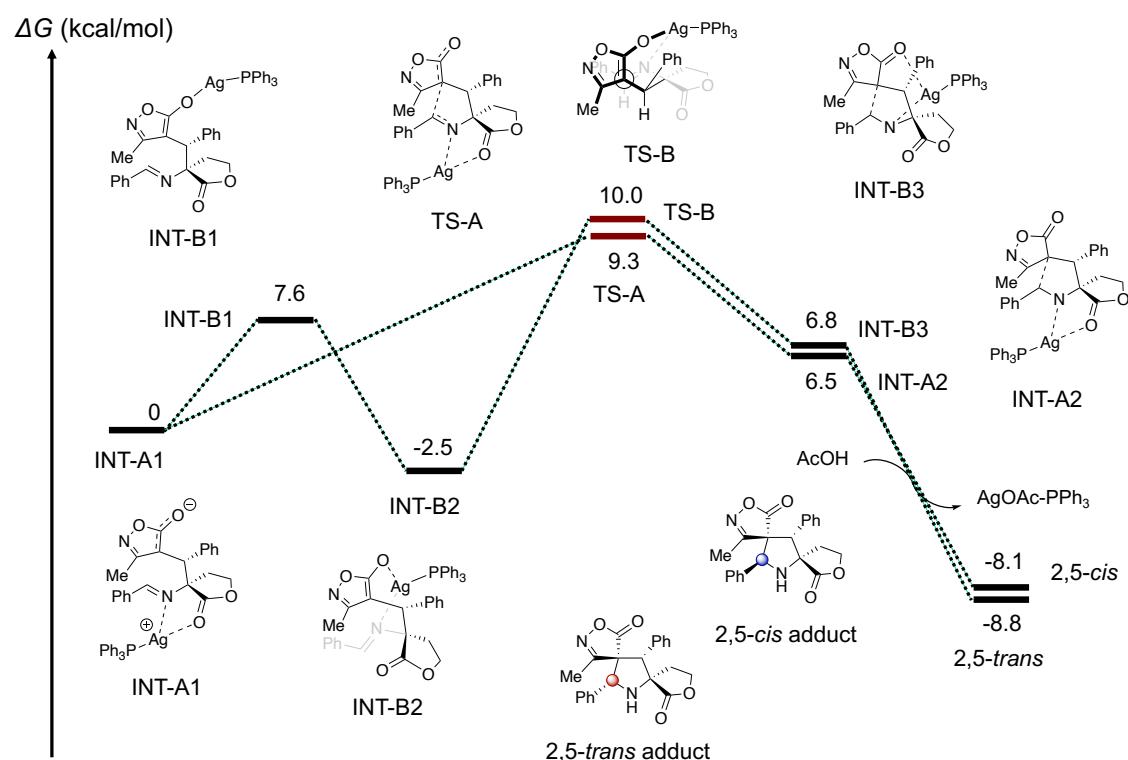

Figure 4-6. The mechanism for the Mannich reaction giving the 2,5-*cis* and 2,5-*trans* adducts under the AgOAc/PPh₃-catalyzed condition (route A and B). The DFT calculations were carried out at B3PW91/LanL2DZ(Ag)+6-31G*(other atoms) with gd3bj level of theory.

The Mannich reaction giving 2,5-*cis* adduct by the direct cyclization from the Michael adduct **INT-A1** was first analyzed (Figure 4-6, route A). As a result, the Gibbs activation energy of the transition state **TS-A** was calculated to be 9.3 kcal/mol. On the other hand, the 2,5-*trans* selective formation would proceed from the intermediate **INT-B2**, which can be formed after the C–N bond rotation of the Michael adduct **INT-A1** (Figure 4-6, route B). The intermediate **INT-B2** has a bidentate coordinate structure to the silver center by its anionic isoxazolone ring moiety and its imine moiety, and the energy was calculated to be $\Delta G = -2.5$ kcal/mol. Thus, the intermediate **INT-B2** has the thermodynamic stability equivalent to the Michael adduct **INT-A1**, and that is much lower than the activation energy of the transition state **TS-A** which affords the 2,5-*cis* adduct. However, the intermediate **INT-B2** may also be formed via the intermediate **INT-B1** in which neither its imine moiety nor its carbonyl group derived from the iminolactone is coordinated, and the energy of this intermediate **INT-B1** was estimated to be $\Delta G = 7.6$ kcal/mol. Also, transition states that should exist between each intermediate were not calculated, because it is considered to be lower than that of Mannich cyclization. The Gibbs activation energy of the transition state **TS-B** which is the Mannich reaction from the intermediate **INT-B2** as the starting material was calculated to be 12.5 kcal/mol, which is comparable to the transition state **TS-A**. These results suggest that the 2,5-*cis* selective process may have a slight kinetic advantage, but the formation of the thermodynamically stable intermediate may have a key role in the 2,5-*trans* selective cycloaddition. However, further calculation studies that consider the actual reaction condition, such as the solvent effect and applying chiral ligand, are necessary to support the origin of the 2,5-*cis/trans* diastereoselectivity enough.

The author next investigated the transformation of the 3-methyl substituted spiropyrrolidines **3aj** to the 4-acetyl substituted pyrrolidines **4aj** by the N–O bond reduction with decarboxylation.¹¹ Examining some conditions,¹² the spiropyrrolidines **3aj** were smoothly transformed to the corresponding 4-acetyl pyrrolidines **4aj** by the action of Pd/C catalyst (10 wt%) in H₂ atmosphere (Figure 4-7). In addition to the reduction proceeding without loss of enantiomeric excess, the retention of the 2,5-*trans* relative

configuration was confirmed by X-ray crystallographic analysis of a single crystal of *rac*-**4aj**. The Pd/C-catalyzed reduction could be applied to several substrates, giving the corresponding 4-acetyl pyrrolidines **4dj** and **4ak** with high yield. On the other hand, 4-benzoyl substrates **4aa** and **4da** could be respectively obtained when MeOH or EtOAc/MeOH was used as the co-solvent because of the low reactivity or solubility of the starting spiropyrrolidines **3aa** and **3da**. Thus, the asymmetric (3+2) cycloaddition of imino lactones **1** with ylidene-isoxazolones **2** and the subsequent N–O bond reduction can access 4-carbonyl pyrrolidines with 2,5-*trans* configuration.

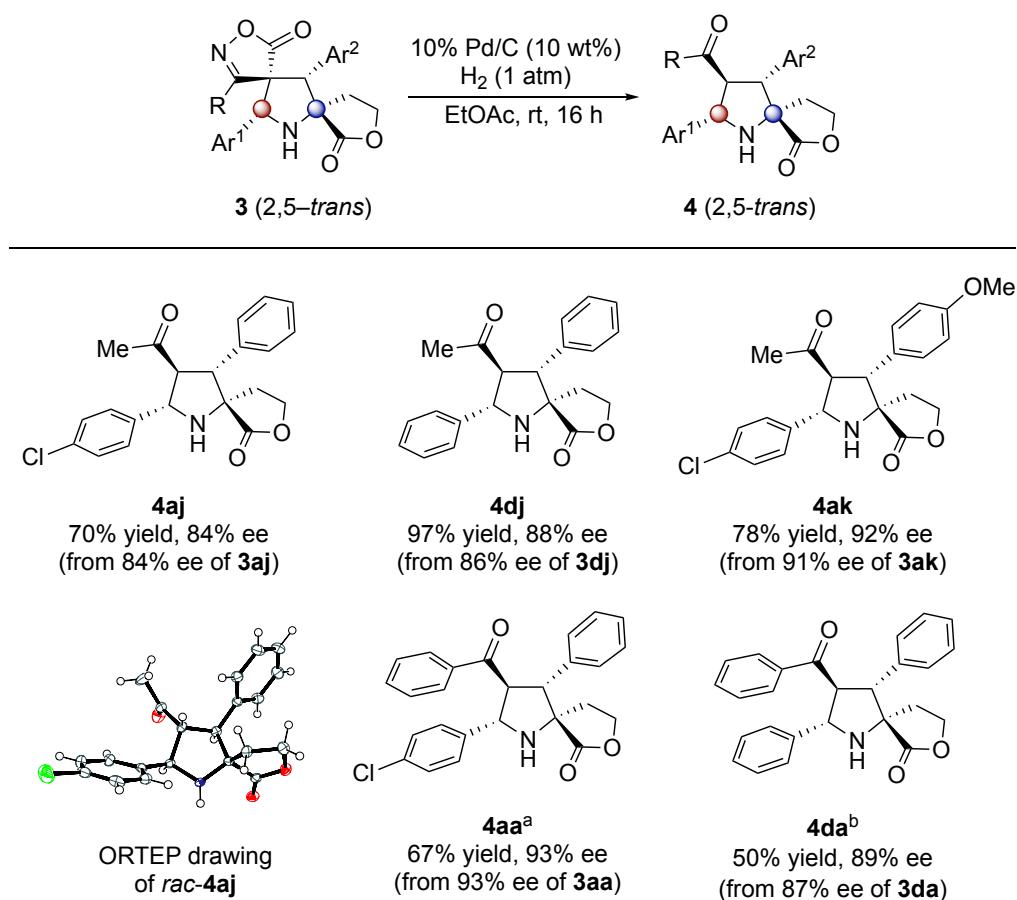

Figure 4-7. Pd/C-catalyzed N–O bond reduction with decarboxylation. [a] MeOH was used as solvent. [b] EtOAc/MeOH was used as co-solvent.

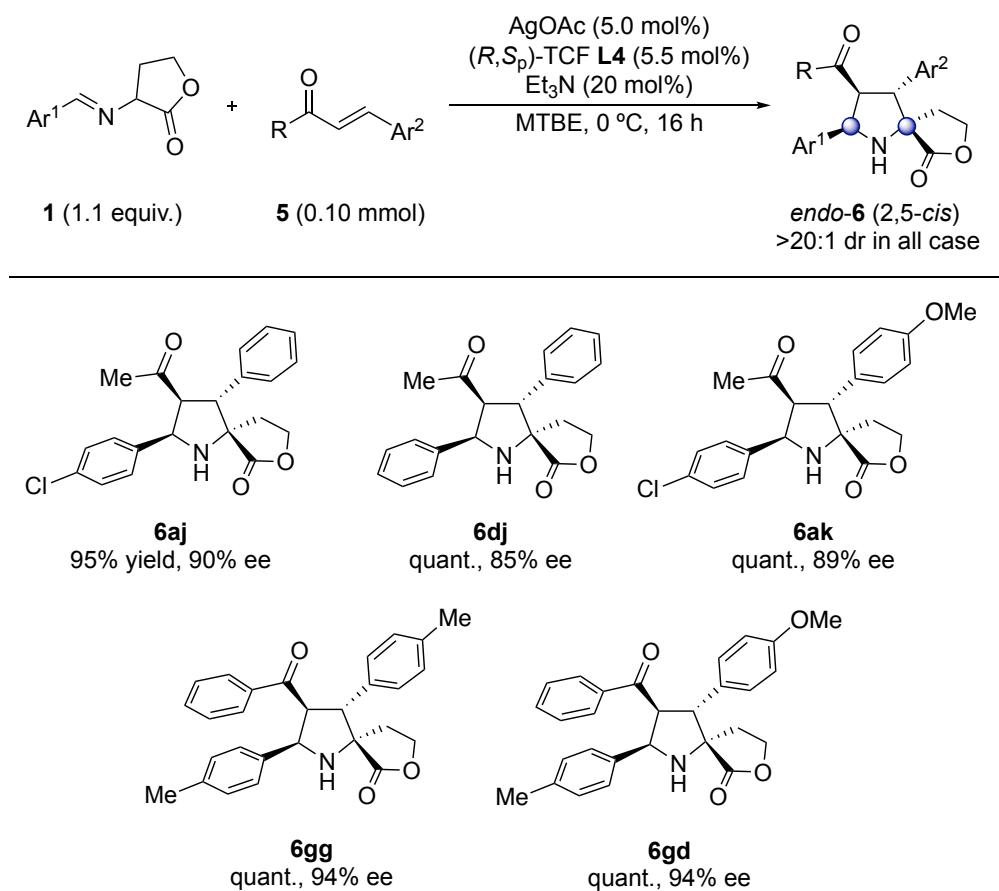

Figure 4-8. 2,5-*cis* Selective synthesis by Ag/TCF-catalyzed 1,3-DC of imino lactones **1** with α,β -unsaturated ketones **5**.

In contrast to the above-described synthesis of 2,5-*trans* pyrrolidines, 2,5-*cis* pyrrolidines were obtained by the reaction using common acyclic-activated olefins.^{4,14} However, the (3+2) cycloaddition of imino lactones **1** with α,β -unsaturated ketones **5** is limited to a copper-catalyzed reaction reported by Wang and co-workers.^{13a} Thus, the author investigated the silver complex-catalyzed (3+2) cycloaddition of imino lactones **1** with α,β -unsaturated ketones **5**. The silver/TCF complex efficiently catalyzed the reaction of imino lactones **1a** with enones **5j**, giving the desired 2,5-*cis* products **6aj** (*endo*-adducts) as a single diastereomer with high enantioselectivity (Figure 4-8). Details of the optimization study are summarized in Table S4-1 (see experimental section). The optimized Ag/TCF-catalyzed reaction condition could be applied to other substrates. For example, both 4-acetyl pyrrolidines **6dj** and **6ak** were quantitatively obtained with high

enantioselectivity from the corresponding starting materials. The *endo*-diastereoselectivity was similar to that in Wang's previous report, and was determined by NMR analysis of the pyrrolidine corresponding to the product **6dj**.^{13a} The absolute configuration was determined by referring to the HPLC analysis of Wang's reported one. Finally, the author investigated whether chalcones could be used in this silver-catalyzed reaction. 4-Benzoyl substituted pyrrolidines with 2,5-*cis* configuration **6gg** and **6gd** were successfully obtained with high enantioselectivity.

4–3. Conclusion

In conclusion, the author has developed a diastereodivergent synthetic method for 2,5-*cis/trans* pyrrolidines using different types of activated olefins. Chiral 2,5-*trans* spiropyrrolidines were obtained by the silver/*iPr*-FcPHOX-catalyzed asymmetric (3+2) cycloaddition of imino lactones **1** with ylidene-isoxazolones **2**. The subsequent reduction of isoxazolone rings proceeded using a Pd/C catalyst, giving the 4-carbonyl pyrrolidines with 2,5-*trans* stereoretention. In contrast, chiral 2,5-*cis* pyrrolidines were synthesized by the silver/TCF-catalyzed asymmetric (3+2) cycloaddition of imino lactones **1** with α,β -unsaturated ketones **5**. This is the first example of the formal diastereodivergent synthesis of 2,5-*cis/trans* pyrrolidines based on a dipolarophile-controlled strategy in the metal-catalyzed asymmetric (3+2) cycloaddition of imino esters.

4–4. Experimental Section

The general information was described in the Experimental Section of Chapter 2.

Unless otherwise stated, all reactions were carried out with oven-dried glassware under the atmosphere of nitrogen. Starting materials, imino lactones **1**,^{12,17} ylidene-isoxazolones **2**,¹⁸ and α,β -unsaturated ketones **5**^{14,19} were prepared and identified by reported methods. Racemic products of **3**, **4**, and **6** were prepared using PPh₃ (5.5 mol%) as the ligand. All other chemical reagents used commercial grade and used as received.

Optimization study of the reaction of imino lactone **1a with enones **5j**.**

[a] Conditions: **1a** (0.11 mmol), **5j** (0.10 mmol), metal salt (5.0 mol%), ligand (5.5 mol%), Et₃N (20 mol%), solvent (1.0 mL), 16 h, rt. [b] Isolated yield. [c] Determined by chiral HPLC analysis. [d] Conducted at 0 °C. [e] Conducted at -20 °C. [f] Without Et₃N.

Silver-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Lactones 1 with Ylidene-Isoxazolones 2. A mixture of AgOCOCF₃ (2.2 mg, 10 μmol, 5.0 mol%) and (S, S_p)-iPr-FcPHOX **L1** (5.3 mg, 11 μmol, 5.5 mol%) was dissolved in dry Et₂O (1.0 mL) at room temperature. To the mixture was added 3Å MS (200 mg), and the mixture was stirred for 30 minutes at the same temperature. After that, imino lactones **1a** (67.1 mg, 0.30 mmol, 1.50 equiv.) and ylidene-isoxazolones **2a** (49.9 mg, 0.20 mmol, 1.00 equiv.). After stirring for 16 h at room temperature, EtOAc (30 mL) was added to the mixture. Then, the mixture was filtered through a short Celite pad and concentrated under reduced pressure. ¹H NMR analysis of the crude product showed that the corresponding cycloadduct was the sole product. The residue was purified by column chromatography (20 g, n-hexane/EtOAc = 2/1) to afford (5R, 6S, 7S, 13R)-13-(4-chlorophenyl)-4,6-diphenyl-2,9-dioxa-3,12-diazadispiro[4.1.4⁷.2⁵]tridec-3-ene-1,8-dione (**3aa**) (88.1 mg, 0.186 mmol, 93.1%, >20:1 dr, 93% ee) as a white solid.

2 mmol Scale Experiment of the Asymmetric (3+2) cycloaddition of Imino Lactones 1a with Ylidene-isoxazolones 2a. A mixture of AgOCOCF₃ (22.1 mg, 0.100 mmol, 5.0 mol%) and (S, S_p)-iPr-FcPHOX **L1** (52.9 mg, 0.110 mmol, 5.5 mol%) was dissolved in dry Et₂O (10.0 mL) at room temperature. To the mixture was added 3Å MS (2.00 g), and the mixture was stirred for 30 minutes at the same temperature. After that, imino lactones **1a** (671 mg, 3.00 mmol, 1.50 equiv.) and ylidene-isoxazolones **2a** (499 mg, 2.00 mmol, 1.00 equiv.). After stirring for 16 h at room temperature, EtOAc (60 mL) was added to the mixture. Then, the mixture was filtered through a short Celite pad and concentrated under reduced pressure. ¹H NMR analysis of the crude product showed that the corresponding cycloadduct was the sole product. The residue was purified by silica gel column chromatography (50 g, n-hexane/EtOAc = 2/1) to afford (5R, 6S, 7S, 13R)-13-(4-chlorophenyl)-4,6-diphenyl-2,9-dioxa-3,12-diazadispiro[4.1.4⁷.2⁵]tridec-3-ene-1,8-dione (**3aa**) (868 mg, 1.84 mmol, 91.8%, >20:1 dr, 93% ee) as a white solid.

(5R, 6S, 7S, 13R)-13-(4-chlorophenyl)-4,6-diphenyl-2,9-dioxa-3,12-diazadispiro[4.1.4⁷.2⁵]tridec-3-ene-1,8-dione (3aa). (88.1 mg, 0.186 mmol, 93.1%,

Typical Procedure for the Preparation of 4-Carbonyl Substituted Pyrrolidines 4 by the Pd/C-catalyzed Decarboxylation of the 2,5-trans Spiropyrrolidines 3. To a solution of the spiropyrrolidines **3aj** (41.1 mg, 0.10 mmol, 1.00 equiv.) in EtOAc (3 mL) was added 10% Pd/C (4.1 mg, 10 wt%) at room temperature, and the mixture was stirred under H₂ (1 atm) atmosphere. After stirring for 16 h at the same temperature, the mixture was diluted with 30 mL EtOAc, filtered through a short Celite pad, and concentrated under reduced pressure. The residue was purified by column chromatography (silica gel, 20 g, *n*-hexane/EtOAc = 2/1) to afford (2*S*, 3*S*, 4*R*, 5*S*)-3-acetyl-2-(4-chlorophenyl)-4-phenyl-7-oxa-1-azaspiro[4.4]nonan-6-one (**4aj**) (25.8 mg, 0.0698 mmol, 69.8%, 85% ee) as a white solid.

(2*S*, 3*S*, 4*R*, 5*S*)-3-acetyl-2-(4-chlorophenyl)-4-phenyl-7-oxa-1-azaspiro[4.4]nonan-6-one (4aj). White solid; mp 138–142 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.42–7.30 (m, 9H), 4.88 (d, 1H, *J* = 9.4 Hz), 4.07–4.01 (m, 1H), 3.99 (d, 1H, *J* = 11.1 Hz), 3.43 (dd, 1H, *J* = 11.0, 9.4 Hz), 3.26–3.20 (m, 1H), 2.23–2.18 (m, 2H), 1.88 (s, 3H); ¹³C NMR (101 MHz, CDCl₃): δ 206.4, 180.1, 140.5, 136.6, 133.7, 129.2, 129.0, 128.5, 128.4, 128.2, 67.9, 65.5, 65.3, 63.0, 56.0, 35.0, 31.3; HPLC (Daicel Chiraldak AD-H, *n*-hexane/2-propanol = 90/10, 1.0 mL/min, 220 nm); *t*_R = 20.1 min (minor), 26.1 min (major); $[\alpha]_D^{25}$ 11.17 (*c* 0.05, CHCl₃); HRMS (ESI) *m/z*: [M+Na]⁺ Calcd for C₂₁H₂₀³⁵ClNNaO₃⁺, 392.1024; found 392.1040. CCDC 2278099 (racemate of **4aj**).

(2*S*, 3*S*, 4*R*, 5*S*)-3-acetyl-2,4-diphenyl-7-oxa-1-azaspiro[4.4]nonan-6-one (4dj). (32.6 mg, 97%, 88% ee); white solid; mp 127–130 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.45 (d, 2H, *J* = 7.1 Hz), 7.39–7.31 (m, 8H), 4.87 (d, 1H, *J* = 9.4 Hz), 4.67–4.01 (m, 2H), 3.55–3.49 (m, 1H), 3.26–3.20 (m, 1H), 2.25–2.21 (m, 2H), 1.88 (s, 3H); ¹³C NMR (101 MHz, CDCl₃): δ 206.6, 180.2, 141.8, 136.7, 129.1, 128.8, 128.5, 128.3, 128.1, 126.9, 67.9, 65.5, 65.3, 63.9, 55.9, 35.1, 31.2; HPLC (Daicel Chiraldak IC-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); *t*_R = 20.3 min (major), 72.5 min (minor); $[\alpha]_D^{25}$ 4.76 (*c* 0.05,

Typical Procedure for the Preparation of 4-Carbonyl Substituted Pyrrolidines 6 by the Silver-Catalyzed endo-Selective Asymmetric (3+2) Cycloaddition of Imino Lactones 1 with α,β -Unsaturated Ketones 5. A mixture of AgOAc (0.83 mg, 5 μ mol, 5.0 mol%) and (R, S_p)-ThioClickFerrophos **L4** (3.5 mg, 5.5 μ mol, 5.5 mol%) was dissolved in dry MTBE (1.0 mL) at room temperature. After stirring for 30 minutes at the same temperature, to the mixture were added imino lactones **1a** (24.6 mg, 0.11 mmol, 1.10 equiv.), dry Et₃N (2.7 μ L, 20 μ mol, 20 mol %), and enones **5j** (24.9 mg, 0.10 mmol, 1.00 equiv.) at 0 °C. After stirring for 16 h at the same temperature, the mixture was diluted with 30 mL EtOAc, filtered through a pad of Celite, and concentrated under reduced pressure. ¹H NMR analysis of the crude product showed that the *endo*-adduct was the sole product. The residue was purified by column chromatography (silica gel, 20 g, *n*-hexane/EtOAc = 2/1) to afford (2*R*, 3*S*, 4*R*, 5*S*)-3-acetyl-2-(4-chlorophenyl)-4-phenyl-7-oxa-1-azaspiro[4.4]nonan-6-one (*endo*-**6aj**) (39.2 mg, 0.0954 mmol, 95.4%, >20:1 dr, 90% ee) as a white solid.

(2*R*, 3*S*, 4*R*, 5*S*)-3-acetyl-2-(4-chlorophenyl)-4-phenyl-7-oxa-1-azaspiro[4.4]nonan-6-one (*endo*-6aj**).** White solid; mp 68–71 °C; ¹H NMR (400 MHz, CDCl₃): δ 7.49 (d, 2H, J = 8.4), 7.37–7.30 (m, 5H), 7.27–7.25 (m, 2H), 4.87 (d, 1H, J = 9.5 Hz), 4.26 (d, 1H, J = 12.4 Hz), 4.07–3.99 (m, 2H), 2.94 (ddd, 1H, J = 10.4, 8.8, 7.3 Hz), 2.37–2.31 (m, 1H), 2.21–2.13 (m, 1H), 1.59 (s, 3H); ¹³C NMR (101 MHz, CDCl₃): δ 206.2, 179.7, 139.0, 135.2, 134.6, 129.55, 129.50, 129.4, 128.7, 128.1, 69.3, 65.8, 63.1, 60.8, 53.8, 33.8, 30.9; HPLC (Daicel Chiralpak IC-3, *n*-hexane/2-propanol = 70/30, 1.0 mL/min, 220 nm); t_R = 9.7 min (major), 11.8 min (minor); $[\alpha]_D^{25}$ –6.23 (c 0.05, CHCl₃); HRMS (ESI) m/z : [M+Na]⁺ Calcd for C₂₁H₂₀³⁵ClNNaO₃⁺, 392.1024; found 392.1040.

X-ray Crystallographic Analysis. The crystallographic data of **3ak** and *rac*-**4aj** were summarized in Table S4-2. Single crystals of **3ak** and *rac*-**4aj** were prepared from CHCl₃ and EtOAc by vapor diffusion technique using *n*-hexane as an anti-solvent, respectively. A suitable single crystal was respectively selected and mounted on the glass fiber and transferred to the goniometer of a Rigaku VariMax Saturn CCD diffractometer with graphite-monochromated MoKα radiation (λ = 71.073 pm). Yadokari-XG 2009 program was used as a graphical interface. The structure was solved and refined by SIR-2004 by SHELX-97 programs. The refinement was performed anisotropically for all non-hydrogen atoms. Hydrogen atoms were placed using AFIX instructions.

In the case of **3ak**, *CrystalStructure* crystallographic software package was used as a graphical interface. The structure was solved and refined by SHELXS Version 2014/5 and SHLEXL Version 2016/6. The difference Fourier maps has suggested that the voids of each crystal were occupied by *n*-hexane molecules, which could not be appropriate because of heavy disorders. The electron density associated with the solvent molecule was removed by SQUEEZE routine of PLATON.

Table S4-2. Crystal data and structure refinements for **3ak** and *rac*-**4aj**.

Compound	3ak	<i>rac</i> - 4aj
CCDC	2278098	2278099

Computational Study.

The computational study was carried out under the same conditions described in the Experimental Section of Chapter 3.

Table S4-3. Total electronic energies (E, in a.u.), thermal correction to Gibbs free energy (TCGFE, in a.u.), and number of imaginary frequencies (NIMAG) in the Mannich reaction of the Michael adduct formed by the (3+2) cycloaddition of ylidene-isoxazolone with azomethine ylide derived from imino lactone **1** and AgOAc/PPh₃ complex.^a

Chapter 5

Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Lactones with Ylidene-pyrazolones

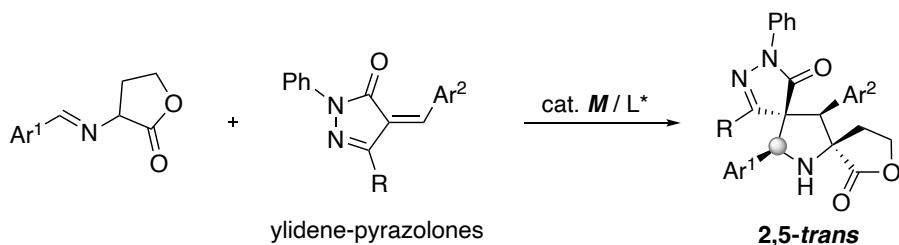

5–1. Introduction

The metal complex-catalyzed 1,3-DC of imino esters with activated olefins is a robust method for stereodivergent preparation of pyrrolidines.¹ Indeed, chiral copper and silver complexes have been developed by many research groups, enabling access to *endo/exo*-diastereomers stereodivergently. However, the 2,5-*trans* configuration in *endo'/exo'*-adducts is still difficult because the generated azomethine ylides are in the *cis*-conformation. To address this issue, a nickel catalyst-controlled strategy that enables access to *exo'*-adducts via stepwise addition/cyclization with bond rotation was proposed by Arai and co-workers.² Huang and co-workers also developed an epimerization strategy; the common 2,5-*cis* selective formation of a pyrrolidine ring and subsequent base-promoted epimerization enabled access to the 2,5-*trans* adducts.³ However, useful methods have rarely been reported except for these pioneering works, and a new methodology is desired for preparing 2,5-*trans* pyrrolidines.^{4,5}

Our research group has engaged in the development of metal complex-catalyzed asymmetric (3+2) cycloaddition of imino esters with activated olefins bearing heterocyclic moieties.⁶ This process revealed that the (3+2) cycloaddition proceeds with 2,5-*trans* diastereoselectivity when ylidene-heterocycles⁷ were employed.⁸ For example, the reaction of imino lactones with ylidene-isoxazolones to afford the 2,5-*trans* pyrrolidines as a single diastereomer was previously accomplished by the author and co-workers, and a chiral silver complex was efficient for the enantioselective synthesis (Chapter 4).^{8b}

The author here focused on pyrazolone rings⁹ which are frequently found in biologically active compounds¹⁰ and whose structure is similar to isoxazolones. Currently, ylidene-pyrazolones are frequently used as suitable Michael acceptors in the asymmetric cycloaddition for constructing spiropyrazolone scaffolds.¹¹ For example, Cai and co-workers previously reported the organocatalytic reaction of imino lactones with ylidene-pyrazolones.¹² Interestingly, it was shown that the rare 2,5-*trans* cycloadducts were

formed, not the common 2,5-*cis* adducts. In this work, the author engaged in the asymmetric (3+2) cycloaddition using ylidene-pyrazolones as the dipolarophiles, which was catalyzed by a metal complex catalyst (Scheme 5-1). As a result, the reaction proceeded with high 2,5-*trans* diastereoselectivity when imino lactones were employed as the azomethine ylide precursors. In addition, a copper/Fesulphos catalyst was shown to be the most suitable for the enantioselective synthesis. These results suggest that the rare 2,5-*trans* diastereoselectivity depended on the heterocyclic structure, not the catalyst used.

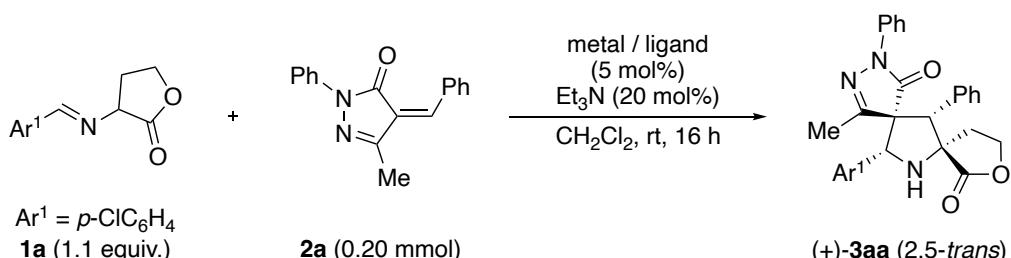

Scheme 5-1. This work: metal-catalyzed 2,5-*trans* selective (3+2) cycloaddition using ylidene-pyrazolones.

5–2. Results and Discussion

The author carried out the asymmetric (3+2) cycloaddition of imino lactones **1a** with ylidene-pyrazolones **2a** in the presence of $[\text{Cu}(\text{MeCN})_4]\text{BF}_4$ (5.0 mol%), PPh_3 (5.5 mol%), and Et_3N (20 mol%) in CH_2Cl_2 at room temperature as an initial experiment. The reaction smoothly gave the corresponding cycloadducts as an almost single diastereomer with a high yield. To reveal the diastereoselectivity, 2-thienyl-substituted spiropyrrolidines *rac*-**3ja** were prepared by the reaction using imino lactones **1j** under the same conditions, and the ^1H NMR spectrum of the product *rac*-**3ja** was compared to the previous report.¹² It was revealed that the same 2,5-*trans* adducts were obtained under the copper complex-catalyzed condition. On the other hand, low diastereoselectivity resulted when acyclic imino esters derived from glycine or alanine were applied to the reaction as the azomethine ylide precursors. Based on these initial experiments, the author decided

to investigate the *2,5-trans* selective asymmetric reaction of imino lactones with ylidene-pyrazolones by using the chiral metal complex catalyst.

[a] Condition: **1a** (0.22 mmol), **2a** (0.20 mmol), metal salt (5.0 mol%), ligand (5.5 mol%), Et_3N (20 mol%), CH_2Cl_2 (1.0 mL), rt, 16 h. [b] Combined yield. [c] Determined by crude ^1H NMR. [d] Determined by chiral HPLC. [e] (*S_p*)-**L1** was used instead of (*R_p*)-**L1**.

Screening of several chiral metal complexes was carried out next. The results are summarized in Table 5-1 and the ligands adopted in this investigation are shown in Figure 5-1. The copper/Fesulphos complex was shown to be the most effective for the enantioselective cycloaddition to give the desired spiropyrazolones (+)-**3aa** with 15:1 dr and 80% ee (Table 5-1, entry 1). When TCF **L2** and FcPHOX **L3** were used under the copper-catalyzed condition, the enantioselectivity was significantly decreased (entries 2, 3). The use of DTBM-Segphos **L4** resulted in good enantioselectivity, but it was not

superior to Fesulphos **L1**. Although the silver complex-catalyzed conditions were also investigated, the enantioselectivity was not increased (entries 5-8). Also, when (*S_p*)-Fesulphos, the enantiomer of (*R_p*)-Fesulphos **L1**, was used under the copper-catalyzed condition, the corresponding enantiomers (–)-**3aa** were smoothly formed with almost the same enantioselectivity (entry 9).

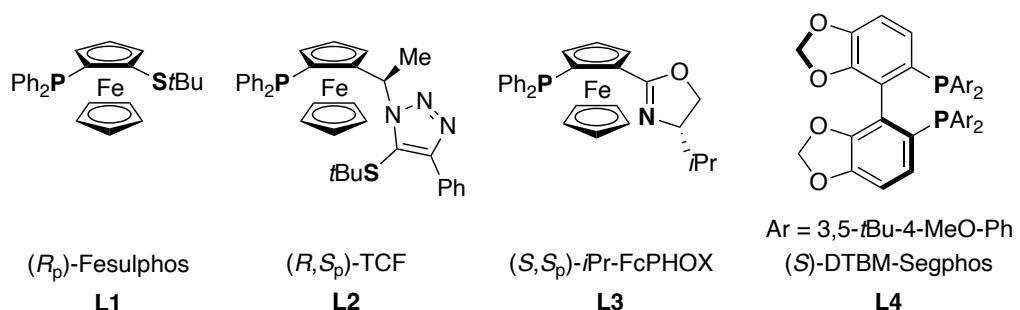

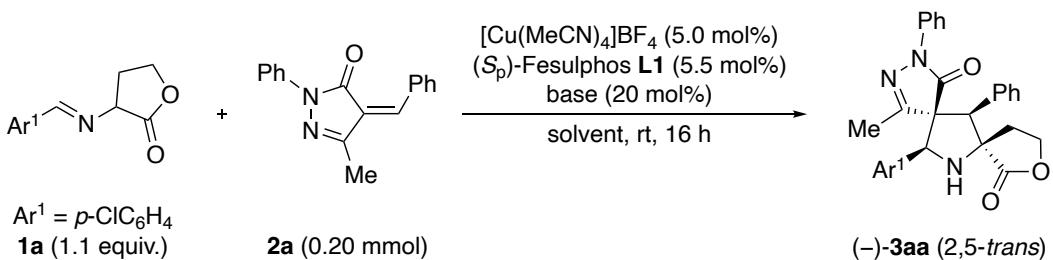

Figure 5-1. Chiral ligands employed in this study.

The optimization study was performed after screening metal complex catalysts, and Table 5-2 summarizes the results. Although several solvents such as THF, Et₂O, MTBE, and toluene were first screened (entries 1-5), CH₂Cl₂ was shown to be the most suitable for the asymmetric reaction (entry 1). Furthermore, screening of additives (bases) revealed that the addition of base affected the enantioselectivity (entries 6-9). For example, the use of DBU largely decreased the enantioselectivity (entry 7). While the reaction without the addition of base improved the enantioselectivity, the cycloadducts (–)-**3aa** were afforded with 94% ee (entry 9). The reaction temperature also had an impact on the enantioselectivity; it increased to 99% ee when the reaction was conducted at 0 °C (entry 10).

9	CH ₂ Cl ₂	none	97	>20:1	94
10 ^e	CH ₂ Cl ₂	none	98	>20:1	99

[a] Condition: **1a** (0.22 mmol), **2a** (0.20 mmol), [Cu(MeCN)₄]BF₄ (5.0 mol%), (S_p)-**L1** (5.5 mol%), base (20 mol%), solvent (1.0 mL), rt, 16 h. [b] Combined yield. [c] Determined by crude ¹H NMR. [d] Determined by chiral HPLC. [e] Conducted at 0°C.

The substrate scope was investigated under the optimal conditions, and various imino lactones **1** could be applied to the copper complex-catalyzed asymmetric (3+2) cycloaddition (Figure 5-2). Imino lactones bearing phenyl, *para*-bromophenyl, and *meta*-chlorophenyl groups gave nearly single 2,5-*trans* diastereomers **3ba**, **3ca**, and **3da** with high enantioselectivity, respectively. However, the methyl group on the phenyl group of imino lactones **1** affected the diastereoselectivity. Although the *meta*- and *para*-methyl substituted cycloadducts **3ea** and **3fa** were produced with excellent stereoselectivity, the *ortho*-methyl substituted one was produced as a mixture of multiple diastereomers and

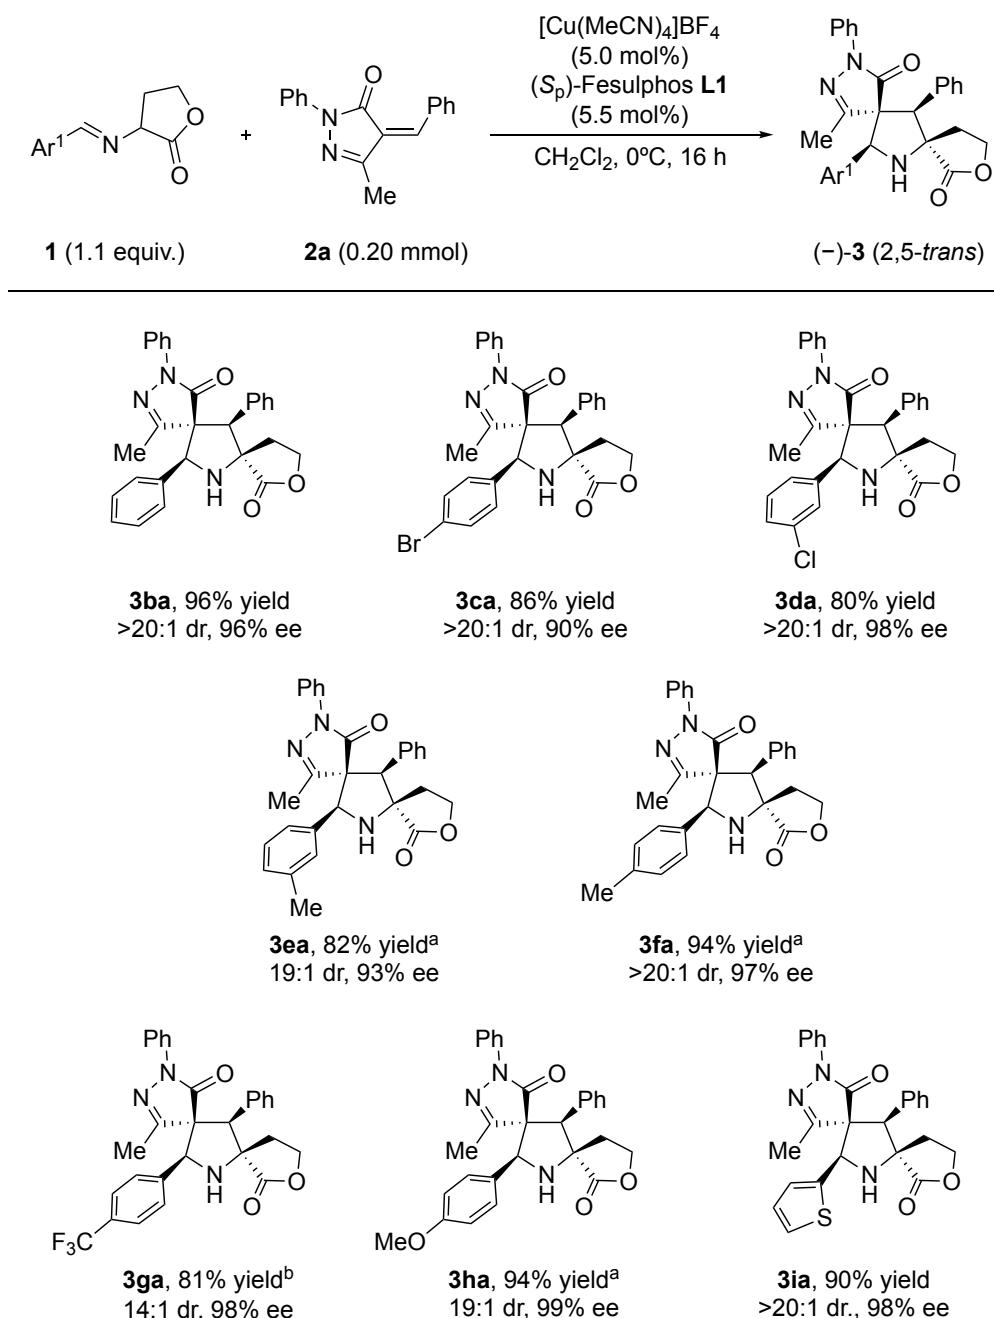

Figure 5-1. Scope of imino lactones **1**. [a] 3 Å MS (100 mg) was added. [b] 1.5 equiv. of imino lactones **1h** was used.

could not be isolated. Although a *para*-CF₃ phenyl group of the imino lactones slightly decreased the reactivity, the enantioselectivity maintained an excellent value of 98% ee. The electron-donating *para*-MeO substituent could also be used in the reaction to give the spiropyrrolidines **3ha** with excellent enantioselectivity. The 2-thienyl substituted

pyrrolidines **3ia** were successfully obtained under this metal-catalyzed condition as well as under the previous organocatalytic condition.¹²

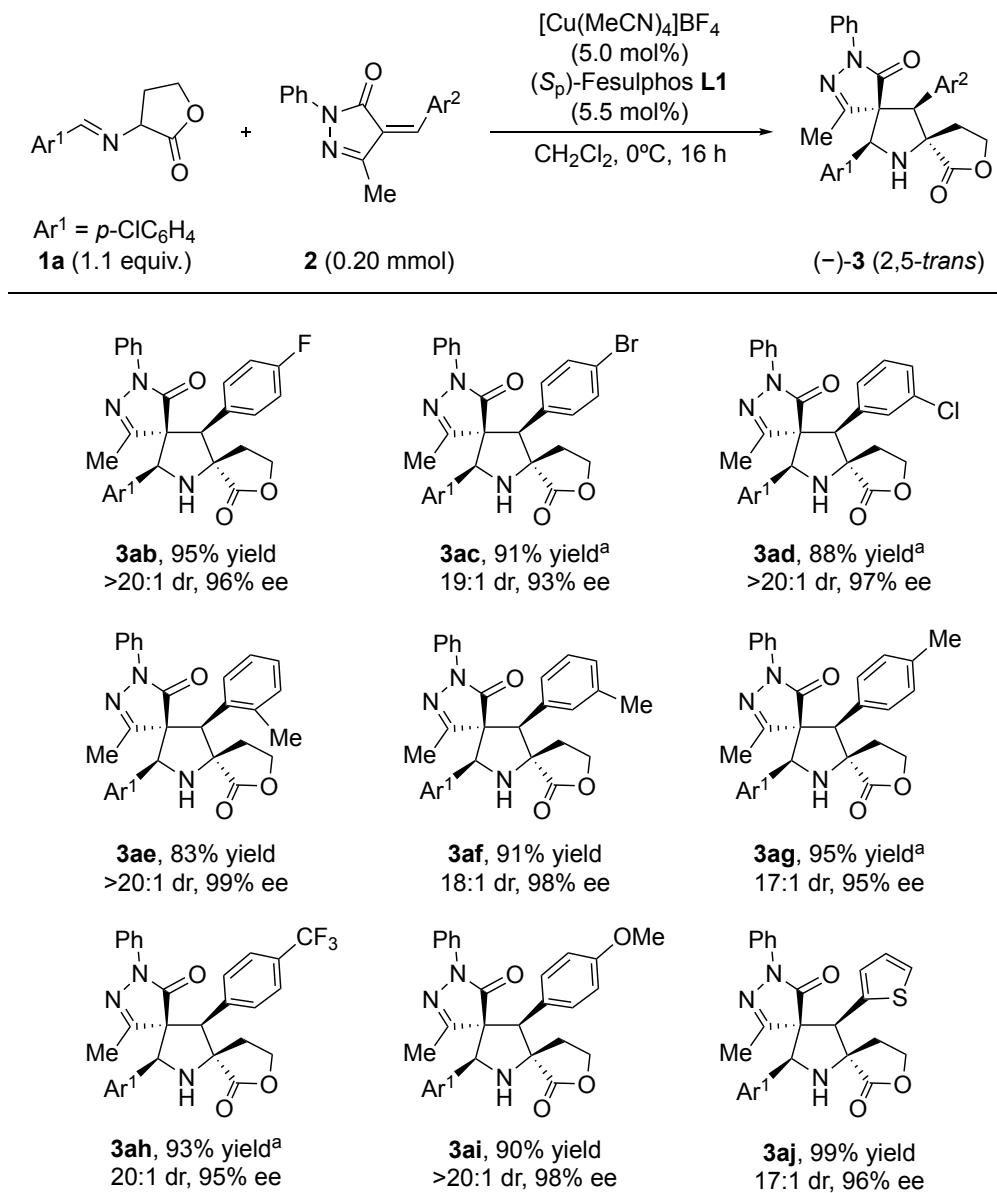

Figure 5-2. Scope of ylidene-pyrazolones **2**. [a] 3 Å MS (100 mg) was added.

The scope of ylidene-pyrazolones **2** was investigated under the optimal conditions, and a wide range of substrates was successfully applied to the stereoselective reaction (Figure 5-3). The reaction of ylidene-pyrazolones bearing the *para*-fluoro, -bromo, and *meta*-chloro substituents on the phenyl group gave the corresponding products **3ab**, **3ac**, and **3ad** with excellent enantioselectivity, respectively. The position of the substituents

had little impact on the yield and stereoselectivity compared to imino lactones **1**, and the *ortho*-, *meta*-, and *para*-methyl substituted products **3ae**, **3af**, and **3ag** were obtained with excellent %ee values. The electronic nature of the substituents had little effect on the results with *para*-CF₃ and *para*-MeO phenyl substituted products **3ah** and **3ai**, which were obtained with excellent stereoselectivities. In addition, the 2-thiophene group could be introduced under the optimized reaction conditions, affording the product **3aj** with 96% ee.

5–3. Conclusion

In conclusion, the author developed a copper complex-catalyzed asymmetric (3+2) cycloaddition of imino lactones with ylidene-pyrazolones. The reaction catalyzed by a copper/Fesulphos catalyst proceeded with high 2,5-*trans* diastereoselectivity and excellent enantioselectivity. Furthermore, a wide range of substrates was successfully applied to the reaction, and the spiropyrazolones bearing various substituents could be obtained under the optimal reaction conditions. The rare 2,5-*trans* diastereoselectivity exhibited a similar trend to the previous organocatalyzed reaction reported by Cai and co-workers,¹² and our previous silver-catalyzed reaction of ylidene-isoxazolones^{8b} also showed the same results. Therefore, the diastereoselectivity is thought to largely depend on the ylidene-heterocycles which are the reaction substrates, not the catalyst.

5–4. Experimental Section

The general information was described in the Experimental Section of Chapter 2.

Unless otherwise stated, all reactions were carried out with oven-dried glassware under atmosphere of nitrogen. with oven-dried glassware. Starting materials, ylidene-pyrazolones **2** were prepared and identified by reported methods.¹³ Racemic products of **3** were prepared using PPh₃ (5.5 mol%) as the ligand. All other chemical reagents used commercial grade and used as received.

Copper-Catalyzed Asymmetric (3+2) Cycloaddition of Imino Lactones 1 with Ylidene-Pyrazolones 2. A mixture of $[\text{Cu}(\text{MeCN})_4]\text{BF}_4$ (3.2 mg, 10 μmol , 5.0 mol%) and (S_p)-*Fesulphos L1* (5.0 mg, 11 μmol , 5.5 mol%) was dissolved in dry CH_2Cl_2 (1.0 mL) and 3 \AA MS (100 mg) was added to the mixture at room temperature. After stirring for 30 minutes, the mixture was cooled to 0°C. Then, imino lactones **1a** (49.2 mg, 0.22 mmol, 1.10 equiv.) and ylidene-pyrazolones **2a** (52.5 mg, 0.20 mmol, 1.00 equiv.). After stirring for 16 h at the same temperature, EtOAc (30 mL) was added to the mixture. Then, the mixture was filtered through a short Celite pad and concentrated under reduced pressure. ^1H NMR analysis of the crude product showed that the corresponding cycloadduct was the sole product. The residue was purified by silica gel column chromatography (20 g, *n*-hexane/EtOAc = 2/1) to afford (*5S,6R,7R,13S*)-13-(4-chlorophenyl)-4-methyl-2,6-diphenyl-9-oxa-2,3,12-triazadispiro[4.1.4⁷.2⁵]tridec-3-ene-1,8-dione (**3aa**) (96.2 mg, 0.198 mmol, 98.4%, >20:1 dr, 99% ee) as a white solid.

Chapter 6

Conclusion and Perspective

The metal-catalyzed asymmetric 1,3-dipolar cycloaddition of imino esters with activated olefins is useful for preparing chiral pyrrolidines in one step. Recently, several methods for diastereodivergent synthesis have been developed by many research groups. Indeed, metal- and ligand-controlled strategies have been frequently reported, and the *endo/exo*-diastereodivergent synthesis of chiral pyrrolidine derivatives has been achieved. Nevertheless, 2,5-*cis/trans* diastereodivergent synthesis has remained challenging because it requires stepwise addition/cyclization with a bond rotation pathway that is usually mechanistically unfavorable. Given this background, the author investigated the asymmetric 1,3-dipolar cycloaddition of imino esters with activated olefins containing heterocyclic moieties, which have rarely been employed in the reaction.

In Chapter 2, the author developed the asymmetric (3+2) cycloaddition using α,β -unsaturated cyclic sulfonic acid esters (sultones) for the asymmetric synthesis of sultone-fused pyrrolidines. A chiral copper catalyst was shown to be efficient for the asymmetric synthesis to afford the desired fused pyrrolidines with high enantioselectivity. In addition, it was revealed that the (3+2) cycloaddition gave *exo*-adducts as a single diastereomer, but in the 2,5-*trans* configuration.

In Chapter 3, the author developed the asymmetric synthesis of spiropyrrolidines by the asymmetric (3+2) cycloaddition of imino esters with ylidene-2,3-dioxopyrrolidines. The reaction was efficiently catalyzed by our original silver/TCF catalyst to give the rare *exo'*-diastereomers with excellent enantioselectivity. Several control experiments suggested that the reaction proceeded via a stepwise addition/cyclization with bond rotation, not via an epimerization pathway after the common 2,5-*cis* selective (3+2) cycloaddition.

In Chapter 4, the author described a new 2,5-*cis/trans*-diastereodivergent synthetic method using ylidene-isoxazolones as ketone equivalents. The reaction of imino lactones with ylidene-isoxazolones was catalyzed by the silver/FcPHOX catalyst to afford the corresponding spiropyrrolidines with high 2,5-*trans* diastereo- and enantioselectivity. The subsequent N–O bond reduction of the isoxazolone ring smoothly gave the 4-carbonyl

pyrrolidines with *2,5-trans* stereoretention. In contrast, the corresponding 4-carbonyl pyrrolidines were obtained as *2,5-cis* diastereomers by the common 1,3-dipolar cycloaddition using α,β -unsaturated ketones.

In Chapter 5, the author developed the asymmetric (3+2) cycloaddition of imino lactones with ylidene-pyrazolones with structures similar to the ylidene-isoxazolones. The reaction also proceeded with *2,5-trans* diastereoselectivities as did the reaction using ylidene-isoxazolones described in Chapter 4. In addition, the enantioselective synthesis was achieved by using the copper/Fesulphos catalyst.

The present study indicated that *2,5-trans* configured pyrrolidines whose formation is mechanistically unfavorable could be obtained by the catalytic asymmetric (3+2) cycloaddition using ylidene-heterocycles. In addition, *2,5-cis/trans* diastereodivergent preparation was shown to be achieved by a dipolarophile-controlled strategy, which uses different types of activated olefins. Both *2,5-cis/trans* substituted pyrrolidines have potential as bioactive compounds. Thus, the author hopes for further studies for applications in drug discovery. Compared to the catalyst-controlled strategy for stereodivergent synthesis, the substrate-controlled strategy has not been well considered. However, this study has shown the potential to gain access to other stereoisomers that are not usually obtained in the cycloaddition reaction. Therefore, further studies into divergent synthesis by the substrate-controlled strategy in other types of cycloadditions and new reagents for easy access to *2,5-trans* adducts are expected to develop. Also, this study indicated that *endo'/exo'*-diastereodivergent synthesis by the catalytic asymmetric cycloaddition of imino esters with activated olefins remains one of the challenging tasks. Although this would be possible if the reaction face of ylidene-heterocycles could be controlled in the first Michael addition step, few examples have been reported to switch the stereoselectivity in the reaction using this type of olefins. Thus, the methods for switching the diastereoselectivity which can be applied to the asymmetric (3+2) cycloaddition using ylidene-heterocycles are desired to develop.

manuscript in preparation.

Acknowledgment

The studies described in this dissertation have been conducted under the guidance of Professor Shin-ichi Fukuzawa of Chuo University at the Department of Applied Chemistry, Institution of Science and Engineering from April 2018 to March 2024. The author would like to express his best gratitude to Professor Shin-ichi Fukuzawa, who has frequently encouraged the author in addition to having stimulating discussions.

The author greatly appreciates Assistant Professor Kazuya Kanemoto for their guidance for the studies, experimental techniques, and valuable suggestions. Associate Professor Ryosuke Haraguchi is also appreciated for the fundamentals of the studies.

The author deeply thanks Project Lecturer Yoshiaki Tanabe of the University of Tokyo at the Department of Applied Chemistry, School of Engineering for his helpfulness in the X-ray crystallographic analysis.

The computation was performed using Research Center for Computational Science, Okazaki, Japan. The author greatly thanks Professor Hirotoshi Mori for teaching him computational chemistry and its techniques.

His laboratory member, Kenji Muroi, is particularly appreciated for helping him with the experiments of this work. The laboratory seniors, Shuma Kato and Tatsuro Yamazaki, and his peers, Koki Torita, Kodai Furuhashi, Yuko Suzuki, Kota Suzuki, Satoshi Kenmochi, and junior members who conducted related studies, Itsuki Ohno, Ayana Inoue, Haruna Araki, Nana Kogai, Kenya Hosono, Yuki Sakuma, are also appreciated for their valuable contributions. The author would like to thank all the other members for their friendship.

Financial support is acknowledged from JSPS as a Grant-in-Aid for JSPS Fellow during his Ph.D. program.

Finally, the author expresses gratitude to his family, particularly to his father Kazutoshi Furuya, and his mother, Mieko, for their encouragement and kind support.

March, 2024
