## 1 Introduction

The analysis of the scattering and diffraction by open－ ended metallic waveguide cavities has been of great in－ terest recently in connection with the prediction and reduction of the radar cross section（RCS）of a target． This problem serves as a simple model of duct structures such as jet engine intakes of aircrafts and cracks occur－ ring on surfaces of general complicated bodies．There－ fore the investigation of a scattering mechanism in case of the existence of open cavities is an important subject in the field of the RCS prediction and reduction．Some of the cavity diffraction problems have been analyzed thus far using a variety of different analytical and nu－ merical methods．If the cavity dimensions are small in comparison to the incident wavelength，numerical tech－ niques such as the method of moments（Senior，1976） and the finite element method（Jeng，1990）can be ap－ plied efficiently．For large cavities with uniform cross sections，the results based on the waveguide modal ap－
proach by the use of the reciprocity relationship and the Kirchhoff approximation have been reported（Altintas， Pathak，and Liang，1988；Ling，Lee，and Chou，1989）． In order to describe systematically the scattering mech－ anism as related to a fairly general class of large cavi－ ties with reasonable accuracy，the three ray－based ap－ proaches，namely，the method of shooting and bouncing rays，the Gaussian beam method，and the generalized ray expansion method have been developed（Ling，Lee， and Chou，1989；Pathak and Burkholder，1991）．Fur－ thermore，hybrid techniques such as the asymptotic／ modal approach and the boundary integral／modal ap－ proach（Ling，1990）have also been established．These hybrid approaches take advantage of the efficiency of the modal analysis as well as the flexibility of asymptotic or numerical techniques．Most of these analysis methods incorporate the scattering from the interior of the cav－ ity including the rim diffraction at the open end，but they do not rigorously take into account the scattering
effect arising from the entire exterior surface of the cavity. Therefore, final solutions due to these approaches are valid only for the restricted range of incidence and observation angles. In addition, these solutions may not be uniformly valid for arbitrary dimensions of the cavity.

The Wiener-Hopf technique is known as a powerful tool for analyzing electromagnetic wave problems associated with canonical geometries, which is mathematically rigorous in the sense that the edge condition is explicitly incorporated into the analysis. Kobayashi (1993) considered a finite parallel-plate waveguide with a planar termination at the open end as an example of simple two-dimensional (2-D) cavity structures, and solved the plane wave diffraction problem rigorously using the Wiener-Hopf technique. As a result, an efficient approximate solution has been obtained, which is valid for the cavity depth greater than the incident wavelength. Kobayashi and Koshikawa (1993, 1994, 1996) have further considered 2-D material-loaded cavities formed by finite and semi-infinite parallel-plate waveguides, and carried out a rigorous RCS analysis by means of the Wiener-Hopf technique. It has been shown by numerical computation that the results are valid over a broad frequency range and can be used as a reference solution for validating more general-purpose computer codes based on approximate methods.

## 2 Development of New Rigorous Methods for a Circular Waveguide Cavity

### 2.1 Vector diffraction problem

We shall generalize the technique, previously developed for a rigorous analysis of the 2-D diffraction by parallel-plate waveguide cavities, to the analysis of the three-dimensional (3-D) vector diffraction by openended cavity structures. Let us consider a semi-infinite circular waveguide with an interior planar termination as shown in Fig. 1 [1-3], where $(\rho, \varphi, z)$ are cylindrical coordinates. It is assumed that the circular cavity is excited by non-symmetric electromagnetic waves of a hypothetical generator with voltage of unit amplitude across an infinitesimally small gap at the interior cylindrical face.

The mixed boundary value problem mentioned above

Fig. 1 Semi-infinite cylinder with an internal plate internal termination
for the wave diffraction by a cylindrical waveguide cavity involves the unknown TM and TE scalar potentials and the problem is stated as follows:

$$
\left(\begin{array}{cc}
\Delta+k^{2} & 0  \tag{1}\\
0 & \Delta+k^{2}
\end{array}\right)\binom{u_{1}(\rho, z)}{u_{2}(\rho, z)}=\binom{0}{0} .
$$

The boundary condition at the cylindrical surface $z \in$ $(-\infty, L)$ with $\rho=b+0$ and $z \in(-L, L)$ with $\rho=b-0$ :

$$
\left(\begin{array}{cc}
\vartheta\left[\partial^{2} / \partial z^{2}+k^{2}\right] & 0  \tag{2a}\\
\vartheta m \rho^{-1} \partial / \partial z & \partial / \partial \rho
\end{array}\right)\binom{u_{1}^{t}}{u_{2}^{t}}=\binom{0}{0} \cdot(2
$$

The boundary condition at the plate termination $\rho \in$ $(0, b), z=-L:$

$$
\left(\begin{array}{cc}
\vartheta m \rho^{-1} \partial / \partial z & \partial / \partial \rho  \tag{2b}\\
\vartheta m \partial^{2} / \partial \rho \partial z & m / \rho
\end{array}\right)\binom{u_{1}^{t}}{u_{2}^{t}}=\binom{0}{0} .
$$

Here $\vartheta=i(\omega \varepsilon)^{-1}$ and $m$ is the number of the azimuth mode.
Taking the Fourier transform of (1) appropriately, we derive the transformed wave equations with unknown inhomogeneous terms comprising the field potentials and their normal derivatives on the surface of the interior planar termination, with the result that

$$
\left(\begin{array}{cc}
\hat{T} & 0 \\
0 & \hat{T} \tag{3}
\end{array}\right)\binom{U_{1}(\rho, \alpha)}{U_{2}(\rho, \alpha)}=\binom{0}{0} \text { in } \rho>b
$$

$$
\begin{aligned}
& \left(\begin{array}{cc}
\hat{T} & 0 \\
0 & \hat{T}
\end{array}\right)\binom{\Phi_{1}(\rho, \alpha)+e^{i \alpha L} \Psi_{1}^{+}(\rho, \alpha)}{\Phi_{2}(\rho, \alpha)+e^{i \alpha L} \Psi_{2}^{+}(\rho, \alpha)}=e^{-i \alpha L} \\
& \times\binom{\tilde{g}_{1}(\rho)-i \alpha \tilde{f}_{1}(\rho)}{\tilde{g}_{2}(\rho)-i \alpha \tilde{f}_{2}(\rho)} \text { in } 0<\rho<b \text { for } \tau>-k_{2},(4)
\end{aligned}
$$

where $\alpha=\operatorname{Re} \alpha+i \operatorname{Im} \alpha(\equiv \sigma+i \tau)$ with $l=1,2, \hat{T}=$ $\left[d^{2} / d \rho^{2}+\rho^{-1} d / d \rho-\left(\gamma^{2}+m^{2} / \rho^{2}\right)\right], \gamma=\left(\alpha^{2}-k^{2}\right)^{1 / 2}$ with $\operatorname{Re} \gamma>0$, and $\tilde{f}_{l}(\rho), \tilde{g}_{l}(\rho)$ are the unknown inhomogeneous terms defined by

$$
\begin{gather*}
\tilde{f}_{l}(\rho)=(2 \pi)^{-1 / 2} u_{l}^{t}(\rho,-L) \\
\tilde{g}_{l}(\rho)=(2 \pi)^{-1 / 2} \partial u_{l}^{t}(\rho, z) /\left.\partial z\right|_{z=-L} \tag{5}
\end{gather*}
$$

The terms on the left-hand sides of (3) and (4) are the Fourier transforms of the unknown functions in (1) and (2), being defined by

$$
\begin{gathered}
U_{l}(\rho, \alpha)=(2 \pi)^{-1 / 2} \int_{-\infty}^{+\infty} u_{l}(\rho, z) e^{i \alpha z} d z, \text { for } \rho>b,(6 \mathrm{a}) \\
U_{l}(\rho, \alpha)=(2 \pi)^{-1 / 2} \int_{-L}^{+\infty} u_{l}(\rho, z) e^{i \alpha z} d z, \text { for } \rho<b,(6 \mathrm{~b}) \\
U_{l}^{+}(\rho, \alpha)=\frac{1}{\sqrt{2 \pi}} \int_{+L}^{+\infty} u_{l}(\rho, z) e^{i \alpha(z-L)} d z,(6 \mathrm{c}) \\
\Phi_{l}(\rho, \alpha)=\frac{1}{\sqrt{2 \pi}} \int_{-L}^{+L} u_{l}^{t}(\rho, z) e^{i \alpha z} d z .(6 \mathrm{~d})
\end{gathered}
$$

It is found that $U_{l}^{+}(\rho, \alpha)$ are regular in the half-plane $\tau>-k_{2}$ and $\Phi_{l}(\rho, \alpha)$ with $l=1,2$ are entire functions. Using the notation as given by (6), we may express $U_{l}(\rho, \alpha)$ as

$$
\begin{equation*}
U_{l}(\rho, \alpha)=\Phi_{l}(\rho, \alpha)+e^{i \alpha L} \Psi_{l}^{+}(\rho, \alpha)-U_{l}^{i}(\rho, \alpha) \tag{7}
\end{equation*}
$$

for $0<\rho<b$, where

$$
\begin{equation*}
\Psi_{l}^{(+)}(\rho, \alpha)=U_{l}^{+}(\rho, \alpha)+Q_{l}^{+}(\rho, \alpha) \tag{8}
\end{equation*}
$$

$Q_{1}^{+}(\rho, \alpha)=\frac{\omega \varepsilon}{(2 \pi)^{3 / 2}} \int_{-\infty+i \varepsilon_{+}}^{+\infty+i \varepsilon_{+}} \frac{I_{m}\left(\gamma_{\beta} \rho\right) e^{i \beta(d-L)}}{\gamma_{\beta}^{2} I_{m}\left(\gamma_{\beta} b\right)} \frac{d \beta}{\alpha-\beta}$,
$U_{1}^{i}(\rho, \alpha)=\frac{\omega \varepsilon e^{-i \alpha L}}{(2 \pi)^{3 / 2}} \int_{-\infty+i \varepsilon_{+}}^{+\infty+i \varepsilon_{+}} \frac{I_{m}\left(\gamma_{\beta} \rho\right) e^{i \beta(d+L)}}{\gamma_{\beta}^{2} I_{m}\left(\gamma_{\beta} b\right)} \frac{d \beta}{\alpha-\beta},(10)$
In (9) and (10) the constant $\varepsilon_{+}$is taken such that $-k_{2}<$ $\varepsilon_{+}<\tau$.

The main idea is to derive the expressions of the functions in (5) in terms of the Fourier-Bessel and Dini series as well as the static terms with common unknown coefficients due to the correct separation of the variables for (1) and (2) and then to account for the interaction of TM and TE waves. This allows finding the field image in Fourier transform domain. Since the scattered field for the region $\rho>b$ must vanish as $\rho \rightarrow \infty$ according to the radiation condition, we find by taking into account the boundary conditions at the termination the solutions of (3) and (4). This leads to a scattered field representation in the Fourier transform domain. Using the boundary conditions for the field components $e_{z}(\rho, z)$, $e_{\varphi}(\rho, z)$ at the cylindrical surfers with $\rho=b$ and the conditions of continuity for the field components $h_{z}(\rho, z)$, $h_{\varphi}(\rho, z)$ with $\rho=b$ and $L<z<\infty$ in the Fourier

Fig. 2 Geometry of the problem
transform domain, we derive the Wiener-Hopf equation as well as the set of linear algebraic equations of the second kind after the factorization and decomposition procedure, which leads to a rigorous solution for arbitrary physical parameters. An approximate solution is further derived for the case where the dominant propagating TE and TM modes consecutively appear in the circular cavity of large depth.

### 2.2 Axially symmetric case

The scalar-type transition under co-phasal distribution of the electric voltage in the generator as well as a generalization of the approach to a more realistic model involving an open-ended finite circular waveguide cavity as shown in Fig. 2 are also investigated [4-6]. The axially symmetric mixed boundary value problem for the above-mentioned problem of wave diffraction by a cylindrical waveguide cavity now involves the unknown TM scalar potential and is stated as follows:

$$
\begin{equation*}
\Delta \phi+k^{2} \phi=0 \tag{11}
\end{equation*}
$$

The boundary condition at the cylindrical surface

$$
\begin{equation*}
z \in(-L, L) \text { with } \rho=b \pm 0:\left[\partial^{2} / \partial z^{2}+k^{2}\right] \phi^{t}=0 \tag{12}
\end{equation*}
$$

The boundary condition at the plate termination

$$
\begin{equation*}
\rho \in(0, b) \text { with } z=-L \pm 0: \partial^{2} / \partial \rho \partial z\left[\phi^{t}\right]=0 \tag{13}
\end{equation*}
$$

Taking the Fourier transform of (11), we derive the transformed wave equations with unknown inhomogeneous terms which comprise the field potential on the opposite surfaces of the planar termination. Expanding these terms into the convergent Fourier-Bessel series and applying the above-mentioned technique, we
obtain the correct field image in the Fourier trans form domain. This allows to formulate the problem in terms of the Wiener-Hopf equation, which is solved via the factorization and decomposition procedure. Finally we obtain the exact solution with the result that

$$
\begin{align*}
& E_{-}(b, \alpha)+M_{-}(\alpha) \\
& \quad \times\left[J_{E}^{(1)}(\alpha)+\sum_{n=1}^{\infty} \frac{M_{+}\left(i \gamma_{n}\right) E_{-}\left(b,-i \gamma_{n}\right)}{i \gamma_{n}\left(\alpha-i \gamma_{n}\right)}\right] \\
& =M_{-}(\alpha) R_{-}(\alpha),  \tag{14}\\
& E_{+}(b, \alpha)-M_{+}(\alpha) \\
& \quad \times\left[J_{E}^{(2)}(\alpha)+\sum_{n=1}^{\infty} \frac{e^{-4 \gamma_{n} L} M_{+}\left(i \gamma_{n}\right) E_{+}\left(b,-i \gamma_{n}\right)}{i \gamma_{n}\left(\alpha+i \gamma_{n}\right)}\right] \\
& =M_{+}(\alpha) R_{+}(\alpha), \tag{15}
\end{align*}
$$

where

$$
\begin{aligned}
& J_{E}^{(1,2)}(\alpha) \\
& =\frac{1}{2} \int_{ \pm k}^{ \pm i \infty \pm k} \frac{e^{ \pm 2 i \nu L} M_{ \pm}(\nu) E_{ \pm}(b, \nu)}{\gamma_{\nu}^{2} K_{0}\left(\gamma_{\nu} b\right)\left[K_{0}\left(\gamma_{\nu} b\right)-i \pi I_{0}\left(\gamma_{\nu} b\right)\right]} \frac{d \nu}{\nu-\alpha} .(16)
\end{aligned}
$$

Here $E_{ \pm}(b, \alpha)$ are the unknown functions in the transform domain for $e_{z}(b, z) ; R_{ \pm}(\alpha)$ and $M_{ \pm}(\alpha)$ are known functions which are regular in the half-planes $\tau_{<}^{>} \mp k_{2}$. In (15), $I_{0}(\cdot)$ and $K_{0}(\cdot)$ are the modified Bessel functions of the first and second kinds, respectively.

The solution is exact but formal, since singular infinite branch-cut integrals (16) with unknown integrands are involved. Then taking into account the exponentially decaying behavior of the integrand (16), we can express $J_{E}^{(1,2)}(\alpha)$ for large $|k| L$ by keeping only the leading term for the asymptotic expansion with the result that,

$$
\begin{align*}
J_{E}^{(1)}(\alpha) & \sim \frac{1}{2} e^{2 i k L} b^{2} \chi(\alpha) M_{+}(k) E_{+}(b, k) \\
J_{E}^{(2)}(\alpha) & \sim \frac{1}{2} e^{2 i k L} b^{2} \chi(-\alpha) M_{+}(k) E_{-}(b,-k) \tag{17}
\end{align*}
$$

where

$$
\begin{equation*}
\chi(\alpha)=\int_{0}^{\infty} \frac{e^{-2 t L}}{[t-i(k-\alpha)] R_{0}(t)} d t \tag{18}
\end{equation*}
$$

with

$$
\begin{align*}
& R_{0}(t)=2 i t k b^{2} K_{0}\left(i^{1 / 2} \sqrt{2 k t b^{2}}\right) \\
& \quad \times\left[K_{0}\left(i^{1 / 2} \sqrt{2 k t b^{2}}\right)-i \pi I_{0}\left(i^{1 / 2} \sqrt{2 k t b^{2}}\right)\right]  \tag{19}\\
& |\alpha-k|>0 \text { and }-\pi / 2<\arg (\alpha-k)<3 \pi / 2 . \tag{20}
\end{align*}
$$

The integral (18) is uniformly convergent because of the integrable singularity $R_{0}(t)=O\left(t(\ln t)^{2}\right)$ for $t \rightarrow 0$ and the conditions (20).

Next we derive the approximate expressions of $E_{-}(\alpha)$ and $E_{+}(\alpha)$ which lead to the two sets of $2 N+2$ equations, where $N$ is a large positive integer. These equations can be solved numerically with high accuracy. Approximation procedures based on a rigorous asymptotics are presented and an approximate solution of the Wiener-Hopf equation is derived. The scattered field inside and outside the cavity is evaluated by taking the inverse Fourier transform and applying the saddle point method of integration.

## 3 Numerical results and discussion

Based on the mentioned above results, we have carried out numerical computations and give representative numerical examples of the radiation patterns for the amplitude of the electric components for various physical parameters. We have computed electric field components $\left|e_{z}^{*}\right|=\left|e_{z}(\rho, z) R\right|$ and $\left|e_{\rho}^{*}\right|=\left|e_{\rho}(\rho, z) R\right|$ as $R \rightarrow \infty$, where $(R, \theta)$ are cylindrical coordinates defined by $z=R \cos \theta, \rho=R \sin \theta$ for $0<\theta<\pi$. Figure 3 shows the far field amplitude of $e_{z}^{*}$ and $e_{\rho}^{*}$ as a function of observation angle. It is seen from the figure that the radiated field oscillates rapidly with an increase of the cavity dimension. This sharp oscillation for larger cavities is due to the effect of the multiple diffraction between the aperture and the back corner. Next we evaluate the power of TM waves radiated from the cavity through the elementary surface $d S=\sin \theta d \theta d \varphi$. The radiated power P is found to be

$$
P(\theta) \sim 0.5(\varepsilon / \mu)^{1 / 2}\left|e_{z}(\rho, z) / \sin \theta\right|^{2} R^{2}
$$

We investigate the power radiated from the cavities as a function of the observation angle and cavity parameters. Figure 4 shows that, with an increase of the cross section of the cavity, dominant peaks of oscillations of the radiated power are formed in the region $75^{\circ}<\theta<105^{\circ}$. The focusing effect of the radiated power is found in the direction $\theta=90^{\circ}$ for short cavities.

Fig. 3 Radiation pattern of electric field components $e_{z}^{*}$ and $e_{\rho}^{*}$ for $d / L=0$. Line 1: $2 b=10 \lambda, L / b=1$. Line 2: $2 b=2 \lambda, L / b=5$.

Fig. 4 Power of the radiation energy for $d / L=0.0$

## 4 Conclusions

We have analyzed the vector diffraction problem for a circular waveguide cavity rigorously using the WienerHopf technique. The method of solution is a generalization of the approach we have established previously for the analysis of the parallel-plate waveguide with a planar termination and it uses the infinite Fourier-Bessel and Dini series in the formulation, and rigorously involves the interaction between TM and TE types of waves. The key equations for investigation of the electromagnetic fields scattered by the cylindrical waveguide cavity in the vector case are derived.

For investigating the axial symmetric electromagnetic fields scattered by the cylindrical waveguide cavity numerically, approximate procedures and an approximate solution of the Wiener-Hopf equation are derived. Based on these results, we have carried out numerical computations and showed representative numerical ex-
amples of the radiation patterns for amplitude of the electric components and the power radiated from the cavities for various physical parameters. Some comparisons with exact solution for infinite and semi infinite cylinders have also been made.
